## 14.5.2. Reading Data from a Sequential-Access Text File

Data is stored in files so that it may be retrieved for processing when needed. [Section 14.5.1](#) demonstrated how to create a file for sequential access. This section shows how to read data sequentially from a text file. In this section, we demonstrate how class `Scanner` can be used to input data from a file rather than the keyboard.

The application in [Fig. 14.11](#) and [Fig. 14.12](#) reads records from the file "`clients.txt`" created by the application of [Section 14.5.1](#) and displays the record contents. Line 13 of [Fig. 14.11](#) declares a `Scanner` that will be used to retrieve input from the file.

Figure 14.11. Sequential file reading using a `Scanner`.

(This item is displayed on pages 690 - 691 in the print version)

```
1 // Fig. 14.11: ReadTextFile.java

8
9 import com.deitel.jhtp6.ch14.AccountRecord;
10
11 public class ReadTextFile
12 {
13 private Scanner input;
14
15 // enable user to open file
16 public void openFile()
17 {
18 try
19 {
20 input = new Scanner(new File("clients.txt"));
21 } // end try
22 catch (FileNotFoundException fileNotFoundException)
23 {
24 System.err.println("Error opening file.");
25 System.exit(1);
26 } // end catch
27 } // end method openFile
28
29 // read record from file
30 public void readRecords()
31 {
32 // object to be written to screen
33 AccountRecord record = new AccountRecord();
34
35 System.out.printf("%-10s%-12s%-12s%10s\n", "Account",
36 "First Name", "Last Name", "Balance");
37
38 try // read records from file using Scanner object
39 {
40 while (input.hasNext())
```

```

41 {
42 record.setAccount(input.nextInt()); // read account number
43 record.setFirstName(input.next()); // read first name
44 record.setLastName(input.next()); // read last name
45 record.setBalance(input.nextDouble()); // read balance
46
47 // display record contents
48 System.out.printf("%-10d%-12s%-12s%10.2f\n",
49 record.getAccount(), record.getFirstName(),
50 record.getLastName(), record.getBalance());
51 } // end while
52 } // end try
53 catch (NoSuchElementException elementException)
54 {
55 System.err.println("File improperly formed.");
56 input.close();
57 System.exit(1);
58 } // end catch
59 catch (IllegalStateException stateException)
60 {
61 System.err.println("Error reading from file.");
62 System.exit(1);
63 } // end catch
64 } // end method readRecords
65
66 // close file and terminate application
67 public void closeFile()
68 {
69 if (input != null)
70 input.close(); // close file
71 } // end method closeFile
72 } // end class ReadTextFile

```

Figure 14.12. Testing the **ReadTextFile** class.

(This item is displayed on page 691 in the print version)

```

1 // Fig. 14.12: ReadTextFileTest.java
2 // This program test class ReadTextFile.
3
4 public class ReadTextFileTest
5 {
6 public static void main(String args[])
7 {
8 ReadTextFile application = new ReadTextFile();
9
10 application.openFile();
11 application.readRecords();
12 application.closeFile();
13 } // end main
14 } // end class ReadTextFileTest

```

| Account | First Name | Last Name | Balance |
|---------|------------|-----------|---------|
| 100     | Bob        | Jones     | 24.98   |
| 200     | Steve      | Doe       | -345.67 |
| 300     | Pam        | White     | 0.00    |
| 400     | Sam        | Stone     | -42.16  |
| 500     | Sue        | Rich      | 224.62  |

Method `openFile` (lines 1627) opens the file for reading by instantiating a `Scanner` object in line 20. We pass a `File` object to the constructor, which specifies that the `Scanner` object will read from the file "`clients.txt`" located in the directory from which the application executes. If the file cannot be found, a `FileNotFoundException` occurs. The exception is handled in lines 2226.

---

[Page 689]

Method `readRecords` (lines 3064) reads and displays records from the file. Line 33 creates `AccountRecord` object `record` to store the current record's information. Lines 3536 display headers for the columns in the application's output. Lines 4051 read data from the file until the end-of-file marker is reached (in which case, method `hasNext` will return `false` at line 40). Lines 4245 use `Scanner` methods `nextInt`, `next` and `nextDouble` to input an integer (the account number), two strings (the first and last names) and a double value (the balance). Each record is one line of data in the file. The values are stored in object `record`. If the information in the file is not properly formed (e.g., there is a last name where there should be a balance), a `NoSuchElementException` occurs when the record is input. This exception is handled in lines 5358. If the `Scanner` was closed before the data was input, an `IllegalStateException` occurs (handled in lines 5963). If no exceptions occur, the record's information is displayed on the screen (lines 4850). Note in the format string in line 48 that the account number, first name and last name are left justified, while the balance is right justified and output with two digits of precision. Each iteration of the loop inputs one line of text from the text file, which represents one record.

---

[Page 690]

---

[Page 692]

Lines 6771 define method `closeFile`, which closes the `Scanner`. Method `main` is defined in [Fig. 14.12](#), in lines 613. Line 8 creates a `ReadTextFile` object, which is then used to open, add records to and close the file (lines 1012).

### 14.5.3. Case Study: A Credit-Inquiry Program

To retrieve data sequentially from a file, programs normally start reading from the beginning of the file and read all the data consecutively until the desired information is found. It might be necessary to process the file sequentially several times (from the beginning of the file) during the execution of a program. Class `Scanner` does not provide the ability to reposition to the beginning of the file. If it is necessary to read the file again, the program must close the file and reopen it.

The program in [Fig. 14.13](#)[Fig. 14.15](#) allows a credit manager to obtain lists of customers with zero balances (i.e., customers who do not owe any money), customers with credit balances (i.e., customers to whom the company owes money) and customers with debit balances (i.e., customers who owe the company money for goods and services received). A credit balance is a negative amount, and a debit balance is a positive amount.

2 // This program tests class CreditInquiry.
3
4 public class CreditInquiryTest
5 {
6 public static void main(String args[])
7 {
8 CreditInquiry application = new CreditInquiry();
9 application.processRequests();
10 } // end main
11 } // end class CreditInquiryTest

```

We begin by creating an `enum` type ([Fig. 14.13](#)) to define the different menu options the user will have. The options and their values are listed in lines 710. Method `getValue` (lines 1922) retrieves the value of a specific `enum` constant.

[Page 693]

[Figure 14.14](#) contains the functionality for the credit-inquiry program, and [Fig. 14.15](#) contains the `main` method that executes the program. The program displays a text menu and allows the credit manager to enter one of three options to obtain credit information. Option 1 (`ZERO_BALANCE`) produces a list of accounts with zero balances. Option 2 (`CREDIT_BALANCE`) produces a list of accounts with credit balances. Option 3 (`DEBIT_BALANCE`) produces a list of accounts with debit balances. Option 4 (`END`) terminates program execution. A sample output is shown in [Fig. 14.16](#).

Figure 14.16. Sample output of the credit-inquiry program in [Fig. 14.15](#).

(This item is displayed on page 696 in the print version)

```

Enter request
1 - List accounts with zero balances
2 - List accounts with credit balances
3 - List accounts with debit balances
4 - End of run

? 1

Accounts with zero balances:

300 Pam White 0.00

Enter request
1 - List accounts with zero balances
2 - List accounts with credit balances
3 - List accounts with debit balances
4 - End of run

? 2

Accounts with credit balances:

200 Steve Doe -345.67

```

```

400 Sam Stone -42.16

Enter request
1 - List accounts with zero balances
2 - List accounts with credit balances
3 - List accounts with debit balances
4 - End of run

? 3

Accounts with debit balances:
100 Bob Jones 24.98
500 Sue Rich 224.62
? 4

```

The record information is collected by reading through the entire file and determining whether each record satisfies the criteria for the account type selected by the credit manager. Method `processRequests` (lines 116139 of [Fig. 14.14](#)) calls method `getRequest` to display the menu options (line 119) and stores the result in `MenuOption` variable `accountType`. Note that `getRequest` translates the number typed by the user into a `MenuOption` by using the number to select a `MenuOption` from array `choices`. Lines 121138 loop until the user specifies that the program should terminate. The `switch` statement in lines 123134 displays a header for the current set of records to be output to the screen. Line 136 calls method `readRecords` (lines 2267), which loops through the file and reads every record.

---

[Page 695]

---

[Page 697]

---

Line 30 of method `readRecords` opens the file for reading with a `Scanner`. Note that the file will be opened for reading with a new `Scanner` object each time this method is called, so that we can again read from the beginning of the file. Lines 3437 read a record. Line 40 calls method `shouldDisplay` (lines 7085) to determine whether the current record satisfies the account type requested. If `shouldDisplay` returns `True`, the program displays the account information. When the end-of-file marker is reached, the loop terminates and line 65 calls the `Scanner`'s `close` method to close the `Scanner` and the file. Notice that this occurs in a `finally` block, which will execute whether or not the file was successfully read. Once all the records have been read, control returns to method `processRequests` and `getRequest` is again called (line 137) to retrieve the user's next menu option. [Figure 14.15](#) contains method `main`, and calls method `processRequests` in line 9.

#### 14.5.4. Updating Sequential-Access Files

The data in many sequential files cannot be modified without the risk of destroying other data in the file. For example, if the name "White" needed to be changed to "Worthington," the old name cannot simply be overwritten because the new name requires more space. The record for `White` was written to the file as

```
300 Pam White 0.00
```

If the record is rewritten beginning at the same location in the file using the new name, the record would be

```
300 Pam Worthington 0.00
```

The new record is larger (has more characters) than the original record. The characters beyond the second "o" in "Worthington" would overwrite the beginning of the next sequential record in the file. The problem here is that fields in a text file and hence records can vary in size. For example, 7, 14, 117, 2074 and 27383 are all `ints` stored in the same number of bytes (4) internally, but they are different-sized fields when displayed on the screen or written to a file as text.

Therefore, records in a sequential-access file are not usually updated in place. Instead, the entire file is usually rewritten. To make the preceding name change, the records before 300 Pam White 0.00 in a

## 14.6. Object Serialization

In Section 14.5 , we demonstrated how to write the individual fields of an `AccountRecord` object into a file as text, and how to read those fields from a file and place their values into an `AccountRecord` object in memory. In the examples, `AccountRecord` was used to aggregate the information for one record. When the instance variables for an `AccountRecord` were output to a disk file, certain information was lost, such as the type of each value. For instance, if the value "3" were read from a file, there is no way to tell if the value came from an `int` , a `String` or a `double` . We have only data, not type information, on a disk. If the program that is going to read this data "knows" what object type the data corresponds to, then the data is simply read into objects of that type. For example, in Section 14.5.2 , we know that we are inputting an `int` (the account number), followed by two `Strings` (the first and last name) and a `double` (the balance). We also know that these values are separated by spaces, with only one record on each line. Sometimes we will not know exactly how the data is stored in a file. In such cases, we would like to read or write an entire object from a file. Java provides such a mechanism, called [object serialization](#) . A so-called [serialized object](#) is an object represented as a sequence of bytes that includes the object's data as well as information about the object's type and the types of data stored in the object. After a serialized object has been written into a file, it can be read from the file and [deserialized](#) that is, the type information and bytes that represent the object and its data can be used to recreate the object in memory.

Classes `ObjectInputStream` and `ObjectOutputStream` , which respectively implement the `ObjectInput` and `ObjectOutput` interfaces, enable entire objects to be read from or written to a stream (possibly a file). To use serialization with files, we initialize `ObjectInputStream` and `ObjectOutputStream` objects with stream objects that read from and write to files objects of classes `FileInputStream` and `FileOutputStream` , respectively. Initializing stream objects with other stream objects in this manner is sometimes called [wrapping](#) the new stream object being created wraps the stream object specified as a constructor argument. To wrap a `FileInputStream` in an `ObjectInputStream` , for instance, we pass the `FileInputStream` object to the `ObjectInputStream` 's constructor.

The `ObjectOutput` interface contains method `writeObject` , which takes an `Object` that implements interface `Serializable` (discussed shortly) as an argument and writes its information to an `OutputStream` . Correspondingly, the `ObjectInput` interface contains method `readObject` , which reads and returns a reference to an `Object` from an `InputStream` . After an object has been read, its reference can be cast to the object's actual type. As you will see in Chapter 24 , Networking, applications that communicate via a network, such as the Internet, can also transmit entire objects across the network.

In this section, we create and manipulate sequential-access files using object serialization. Object serialization is performed with byte-based streams, so the sequential files created and manipulated will be binary files. Recall that binary files cannot be viewed in standard text editors. For this reason, we write a separate application that knows how to read and display serialized objects.

### 14.6.1. Creating a Sequential-Access File Using Object Serialization

We begin by creating and writing serialized objects to a sequential-access file. In this section, we reuse much of the code from Section 14.5 , so we focus only on the new features.

#### Defining the `AccountRecordSerializable` Class

Let us begin by modifying our `AccountRecord` class so that objects of this class can be serialized. Class `AccountRecordSerializable` (Fig. 14.17 ) implements interface `Serializable` (line 7), which allows objects of `AccountRecordSerializable` to be serialized and deserialized with `ObjectOutputStreams` and

`ObjectInputStream` . Interface `Serializable` is a [tagging interface](#) . Such an interface contains no methods. A class that implements `Serializable` is [tagged](#) as being a `Serializable` object. This is important because an `ObjectOutputStream` will not output an object unless it *is a* `Serializable` object, which is the case for any object of a class that implements `Serializable` .

---

Figure 14.17. **AccountRecordSerializable** class for serializable objects.

(This item is displayed on pages 699 - 700 in the print version)

```
1 // Fig. 14.17: AccountRecordSerializable.java
2 // A class that represents one record of information.
3 package com.deitel.jhttp6.ch14; // packaged for reuse
4
5 import java.io.Serializable;
6
7 public class AccountRecordSerializable implements Serializable
8 {
9 private int account;
10 private String firstName;
11 private String lastName;
12 private double balance;
13
14 // no-argument constructor calls other constructor with default values
15 public AccountRecordSerializable()
16 {
17 this (0, "", "", 0.0);
18 } // end no-argument AccountRecordSerializable constructor
19
20 // four-argument constructor initializes a record
21 public AccountRecordSerializable(
22 int acct, String first, String last, double bal)
23 {
24 setAccount(acct);
25 setFirstName(first);
26 setLastName(last);
27 setBalance(bal);
28 } // end four-argument AccountRecordSerializable constructor
29
30 // set account number
31 public void setAccount(int acct)
32 {
33 account = acct;
34 } // end method setAccount
35
36 // get account number
37 public int getAccount()
38 {
39 return account;
40 } // end method getAccount
41
42 // set first name
43 public void setFirstName(String first)
44 {
45 firstName = first;
46 } // end method setFirstName
47
48 // get first name
```

```

49 public String getFirstName()
50 {
51 return firstName;
52 } // end method getFirstName
53
54 // set last name
55 public void setLastName(String last)
56 {
57 lastName = last;
58 } // end method setLastName
59
60 // get last name
61 public String getLastName()
62 {
63 return lastName;
64 } // end method getLastName
65
66 // set balance
67 public void setBalance(double bal)
68 {
69 balance = bal;
70 } // end method setBalance
71
72 // get balance
73 public double getBalance()
74 {
75 return balance;
76 } // end method getBalance
77 } // end class AccountRecordSerializable

```

---

In a class that implements `Serializable`, the programmer must ensure that every instance variable of the class is a `Serializable` type. Any instance variable that is not serializable must be declared `transient` to indicate that it is not `Serializable` and should be ignored during the serialization process. By default, all primitive-type variables are serializable. For variables of reference types, you must check the definition of the class (and possibly its superclasses) to ensure that the type is `Serializable`. By default, array objects are serializable. However, if the array contains references to other objects, those objects may or may not be serializable.

Class `AccountRecordSerializable` contains `private` data members `account`, `firstName`, `lastName` and `balance`. This class also provides `public` *get* and *set* methods for accessing the `private` fields.

Now let us discuss the code that creates the sequential-access file (Fig. 14.18 Fig. 14.19). We concentrate only on new concepts here. As stated in Section 14.3, a program can open a file by creating an object of stream class `FileInputStream` or `FileOutputStream`. In this example, the file is to be opened for output, so the program creates a `FileOutputStream` (line 21 of Fig. 14.18). The string argument that is passed to the `FileOutputStream`'s constructor represents the name and path of the file to be opened. Existing files that are opened for output in this manner are truncated. Note that the `.ser` file extension is used we use this file extension for binary files that contain serialized objects.

Figure 14.18. Sequential file created using `ObjectOutputStream`.

(This item is displayed on pages 701 - 702 in the print version)

```

1 // Fig. 14.18: CreateSequentialFile.java
2 // Writing objects sequentially to a file with class ObjectOutputStream.

```

```

64 output.writeObject(record); // output record
65 } // end if
66 else
67 {
68 System.out.println(
69 "Account number must be greater than 0.");
70 } // end else
71 } // end try
72 catch (IOException ioException)
73 {
74 System.err.println("Error writing to file.");
75 return;
76 } // end catch
77 catch (NoSuchElementException elementException)

## Common Programming Error 14.2

*It is a logic error to open an existing file for output when, in fact, the user wishes to preserve the file.*

Class `FileOutputStream` provides methods for writing `byte` arrays and individual `bytes` to a file. In this program we wish to write objects to a file a capability not provided by `FileOutputStream`. For this reason, we wrap a `FileOutputStream` in an `ObjectOutputStream` by passing the new `FileOutputStream` object to the `ObjectOutputStream`'s constructor (lines 2021). The `ObjectOutputStream` object uses the `FileOutputStream` object to write objects into the file. Lines 2021 might throw an `IOException` if a problem occurs while opening the file (e.g., when a file is opened for writing on a drive with insufficient space or when a read-only file is opened for writing). If so, the program displays an error message (lines 2326). If no exception occurs, the file is open and variable `output` can be used to write objects to the file.

This program assumes that data is input correctly and in the proper record-number order. Method `addRecords` (lines 3086) performs the write operation. Lines 6263 create an `AccountRecordSerializable` object from the data entered by the user. Line 64 calls `ObjectOutputStream` method `writeObject` to write the `record` object to the output file. Note that only one statement is required to write the entire object.

---

[Page 704]

Method `closeFile` (lines 89101) closes the file. Method `closeFile` calls `ObjectOutputStream` method `close` on `output` to close both the `ObjectOutputStream` and its underlying `FileOutputStream` (line 94). Note that the

call to method `close` is contained in a `try` block. Method `close` throws an `IOException` if the file cannot be closed properly. In this case, it is important to notify the user that the information in the file might be corrupted. When using wrapped streams, closing the outermost stream also closes the underlying file.

In the sample execution for the program in Fig. 14.19 , we entered information for five accounts the same information shown in Fig. 14.10 . The program does not show how the data records actually appear in the file. Remember that now we are using binary files, which are not humanly readable. To verify that the file has been created successfully, the next section presents a program to read the file's contents.

## 14.6.2. Reading and Deserializing Data from a Sequential-Access File

As discussed in Section 14.5.2 , data is stored in files so that it may be retrieved for processing when needed. The preceding section showed how to create a file for sequential access using object serialization. In this section, we discuss how to read serialized data sequentially from a file.

The program in Fig. 14.20 Fig. 14.21 reads records from a file created by the program in Section 14.6.1 and displays the contents. The program opens the file for input by creating a `FileInputStream` object (line 21). The name of the file to open is specified as an argument to the `FileInputStream` constructor. In Fig. 14.18 , we wrote objects to the file, using an `ObjectOutputStream` object. Data must be read from the file in the same format in which it was written. Therefore, we use an `ObjectInputStream` wrapped around a `FileInputStream` in this program (lines 20-21). If no exceptions occur when opening the file, variable `input` can be used to read objects from the file.

---

---

The program reads records from the file in method `readRecords` (lines 3060). Line 40 calls `ObjectInputStream` method `readObject` to read an `Object` from the file. To use `AccountRecordSerializable` - specific methods, we downcast the returned `Object` to type `AccountRecordSerializable`. Method `readObject` throws an `EOFException` (processed at lines 4851) if an attempt is made to read beyond the end of the file. Method `readObject` throws a `ClassNotFoundException` if the class for the object being read cannot be located. This might occur if the file is accessed on a computer that does not have the class. Figure 14.21 contains method `main` (lines 613), which opens the file, calls method `readRecords` and closes the file.

## 14.7. Random-Access Files

So far, we have seen how to create and manipulate sequential-access files. Sequential-access files are inappropriate for so-called [instant-access applications](#), in which the desired information must be located immediately. Some popular instant-access applications are airline-reservation systems, banking systems, point-of-sale systems, automated teller machines (ATMs) and other kinds of [transaction-processing systems](#) that require rapid access to specific data. The bank at which you have your account may have hundreds of thousands, or even millions, of other customers, but when you use an ATM, the bank determines in seconds whether your account has sufficient funds for the transaction. This kind of instant access is possible with [random-access files](#) and with databases ([Chapter 25](#)). A program can access individual records of a random-access file directly (and quickly) without searching through other records. Random-access files are sometimes called [direct-access files](#).

Recall from [Section 14.5](#) that Java does not impose structure on a file, so an application that wants to use random-access files must specify the format of those files. Several techniques can be used to create random-access files. Perhaps the simplest is to require that all the records in a file be of the same fixed length. Using fixed-length records makes it easy for a program to calculate (as a function of the record size and the record key) the exact location of any record relative to the beginning of the file. We soon see how this capability facilitates direct access to specific records, even in large files.

[Figure 14.22](#) illustrates Java's view of a random-access file composed of fixed-length records. (Each record in this figure is 100 bytes long.) A random-access file is like a railroad train with many cars—some empty, some with contents.

Figure 14.22. Java's view of a random-access file.

[\[View full size image\]](#)

A program can insert data in a random-access file without destroying the other data in the file. Similarly, a program can update or delete data stored previously without rewriting the entire file. In the following sections, we explain how to create a random-access file, enter data, read the data both sequentially and randomly, update the data and delete the data.

### 14.7.1. Creating a Random-Access File

A **RandomAccessFile** is useful for direct-access applications. With a sequential-access file, each successive input/output request reads or writes the next consecutive set of data in the file. With a random-access file, each successive input/output request could be directed to any part of the file perhaps a section widely separated from the part referenced in the previous request. Direct-access applications provide rapid access to specific data items in large files, but users often have to wait for answers. In many instances, however, answers must be made available quickly, to prevent people from becoming impatient and taking their business elsewhere.

**RandomAccessFile** objects have all the capabilities of classes **FileInputStream** and **FileOutputStream**, as well as the capabilities described by interfaces **DataInput** and **DataOutput**. These interfaces provide methods for reading and writing primitive-type values, **byte** arrays and strings. When a program associates an object of class **RandomAccessFile** with a file, the program reads or writes data, beginning at the location in the file specified by the **file-position pointer** (the byte number of the next byte in the file to be read or written to), and manipulates all the data as primitive types. When writing an **int** value, four bytes are output to the file. When reading a **double** value, eight bytes are input from the file. The size of the types is guaranteed, because Java has fixed representations and sizes for all primitive types, regardless of the computing platform.

---

[Page 708]

Random-access file-processing programs rarely write a single field to a file. Normally they write one object at a time, as we show in the upcoming examples. Consider the following problem:

*Create a transaction-processing program capable of storing up to 100 fixed-length records for a company that can have up to 100 customers. Each record should consist of an account number (that will be used as the record key), a last name, a first name and a balance. The program should be able to update an account, insert a new account and delete an account.*

The next several sections introduce the techniques necessary to create this credit-processing program. [Figure 14.23](#) contains the **RandomAccessAccountRecord** class that is used by the next four programs for both reading records from and writing records to a file. Class **RandomAccessAccountRecord** inherits our **AccountRecord** implementation ([Fig. 14.6](#)), which includes **private** fields **account**, **lastName**, **firstName** and **balance** as well as **set** and **get** methods for each field. We could inherit from either **AccountRecord** or **AccountRecordSerializable**. We do not use object serialization when processing random-access files in this chapter, so we inherit from class **AccountRecord**. Note that the class is in package **com.deitel.jhtp6.ch14**.

---

[Page 709]

Figure 14.23. **RandomAccessAccountRecord** class used in random-access file programs.

(This item is displayed on pages 708 - 709 in the print version)

```
1 // Fig. 14.23: RandomAccessAccountRecord.java
2 // Subclass of AccountRecord for random-access file programs.
3 package com.deitel.jhtp6.ch14; // packaged for reuse
4
5 import java.io.RandomAccessFile;
6 import java.io.IOException;
7
8 public class RandomAccessAccountRecord extends AccountRecord
9 {
10 public static final int SIZE = 72;
11
12 // no-argument constructor calls other constructor with default values
13 public RandomAccessAccountRecord()
14 {
```

```

15 this (0, "", "", 0.0);
16 } // end no-argument RandomAccessAccountRecord constructor
17
18 // initialize a RandomAccessAccountRecord
19 public RandomAccessAccountRecord(int account, String firstName,
20 String lastName, double balance)
21 {
22 super(account, firstName, lastName, balance);
23 } // end four-argument RandomAccessAccountRecord constructor
24
25 // read a record from specified RandomAccessFile
26 public void read(RandomAccessFile file) throws IOException
27 {
28 setAccount(file.readInt());
29 setFirstName(readName(file));
30 setLastName(readName(file));
31 setBalance(file.readDouble());
32 } // end method read
33
34 // ensure that name is proper length
35 private String readName(RandomAccessFile file) throws IOException
36 {
37 char name[] = new char[15], temp;
38
39 for (int count = 0; count < name.length; count++)
40 {
41 temp = file.readChar();
42 name[count] = temp;
43 } // end for
44
45 return new String(name).replace('\\0', ' ');
46 } // end method readName
47
48 // write a record to specified RandomAccessFile
49 public void write(RandomAccessFile file) throws IOException
50 {
51 file.writeInt(getAccount());
52 writeName(file, getFirstName());
53 writeName(file, getLastName());
54 file.writeDouble(getBalance());
55 } // end method write
56
57 // write a name to file; maximum of 15 characters
58 private void writeName(RandomAccessFile file, String name)
59 throws IOException
60 {
61 StringBuffer buffer = null;
62
63 if (name != null)
64 buffer = new StringBuffer(name);
65 else
66 buffer = new StringBuffer(15);
67
68 buffer.setLength(15);
69 file.writeChars(buffer.toString());
70 } // end method writeName
71 } // end class RandomAccessAccountRecord

```

Finally, this example also introduces class `StringBuffer`, a class that allows us to dynamically manipulate strings. Class `String` provides many capabilities for processing strings. However, `String` objects are immutable; their character contents cannot be changed after they are created. Class `StringBuffer` provides features for creating and manipulating dynamic string information—that is, modifiable strings. Every `StringBuffer` is capable of storing a number of characters specified by its capacity. If the capacity of a `StringBuffer` is exceeded, the capacity is expanded to accommodate the additional characters. We use class `StringBuffer` to specify the size of a person's first or last name. We discuss class `StringBuffer` in more detail in [Section 14.8](#), as well as in [Chapter 29](#), Strings, Characters and Regular Expressions.

---

[Page 710]

Line 10 declares the constant `SIZE` to represent the size, in bytes, of a record. A `RandomAccessAccountRecord` contains an `int` (4 bytes), two strings that we restrict to 15 characters each (30 bytes for the first name, 30 bytes for the last name) for this example and a `double` (8 bytes), for a total of 72 bytes.

Method `read` (lines 2632) reads one record from the `RandomAccessFile` specified as its argument. `RandomAccessFile` methods `readInt` (line 28) and `readDouble` (line 31) read the `account` and `balance`, respectively. Lines 2930 call utility method `readName` (lines 3546) twice to obtain the first and last names. Method `readName` reads 15 characters from the `RandomAccessFile` and returns a `String`. If a name is shorter than 15 characters, the extra characters have the default value `'\0'` the default for a `char`. Swing GUI components, such as `JTextFields`, cannot display null-byte characters; instead, they display them as rectangles. Line 45 solves this problem by using `String` method `replace` to replace null bytes with spaces. Although our program does not use a GUI, we added this capability for those who wish to reuse this class in a GUI program.

Method `write` (lines 4955) outputs one record to the `RandomAccessFile` specified as its argument. This method uses `RandomAccessFile` method `writeInt` to output the integer `account`, method `writeChars` (called from utility method `writeName` in line 69) to output the `firstName` and `lastName` character arrays, and method `writeDouble` to output the `double` `balance`. [*Note:* To ensure that all the records in the `RandomAccessFile` are the same size, we write exactly 15 characters for the first name and exactly 15 for the last name.] Method `writeName` (lines 5870) performs the write operations for the first and last names. Lines 6366 create a `StringBuffer` that is initialized with either the `name` specified as an argument or with 15 to specify the size of the `StringBuffer` if `name` is `null`. Line 68 sets the number of characters in the `StringBuffer`. If a name is longer than 15 characters, it will be truncated to 15 characters. If a name is smaller than 15 characters it will be set to have 15 characters, with null characters (`'\0'`) to fill the extra space.

[Figure 14.24](#)[Fig. 14.25](#) illustrates the process of opening a random-access file and writing data to the disk. This program writes 100 blank `RandomAccessAccountRecords`. Each `RandomAccessAccountRecord` object contains 0 for the account number, `null` for the last name, `null` for the first name and 0.0 for the balance. The file is initialized to create the proper amount of "empty" space in which the account data will be stored and to enable us to determine in subsequent programs whether each record is empty or contains data.

Figure 14.24. Random-access file created sequentially.

(This item is displayed on page 711 in the print version)

15 RandomAccessFile file = null;
16
17 try // open file for reading and writing
18 {
19 file = new RandomAccessFile("clients.dat", "rw");
20
21 RandomAccessAccountRecord blankRecord =
22 new RandomAccessAccountRecord();
23
24 // write 100 blank records
25 for (int count = 0 ; count < NUMBER_RECORDS; count++)
26 blankRecord.write(file);
27
28 // display message that file was created
29 System.out.println("Created file clients.dat.");
30
31 System.exit(0); // terminate program
32 } // end try
33 catch (IOException ioException)
34 {
35 System.err.println("Error processing file.");
36 System.exit(1);
37 } // end catch
38 finally
39 {
40 try
41 {
42 if (file != null)
43 file.close(); // close file
44 } // end try
45 catch (IOException ioException)
46 {
47 System.err.println("Error closing file.");
48 System.exit(1);
49 } // end catch
50 } // end finally
51 } // end method createFile
52 } // end class CreateRandomFile

```

Figure 14.25. Testing class **CreateRandomFile**.

```

1 // Fig. 14.25: CreateRandomFileTest.java
2 // Testing class CreateRandomFile.
3
4 public class CreateRandomFileTest
5 {
6 public static void main(String args[])
7 {
8 CreateRandomFile application = new CreateRandomFile();
9 application.createFile();
10 } // end main
11 } // end class CreateRandomFileTest

```

Created file clients.dat.

Line 19 of [Fig. 14.24](#) attempts to open a `RandomAccessFile` for use in this program. The `RandomAccessFile` constructor accepts two arguments—the file name and the **file-open mode**. The file-open mode for a `RandomAccessFile` is either `"r"` (to open the file for reading) or `"rw"` (to open the file for reading and writing). Once again, we have used a new file extension (`.dat`). We use this file extension for binary files that do not use object serialization.

[Page 712]

If an `IOException` occurs while opening the file, the program displays a message and terminates. If the file opens properly, lines 2526 invoke `RandomAccessAccountRecord` method `write` 100 times. This method causes the fields of object `blankRecord` to be written to the file associated with `RandomAccessFile` object `file`. Then line 43 closes the file. The code for closing the file is placed in its own `try` statement if an attempt to close the file generates an `IOException`, this exception is caught in lines 4549. [Figure 14.25](#) begins the execution of the program with method `main` (lines 610). Line 8 creates a `CreateRandomFile` object and line 9 calls its `createFile` method to create the file of 100 blank records.

## 14.7.2. Writing Data Randomly to a Random-Access File

The application in [Fig. 14.26](#)[Fig. 14.27](#) writes data to a file that is opened with the `"rw"` mode (for reading and writing). It uses `RandomAccessFile` method `seek` to position to the exact location in the file at which a record of information is stored. Method `seek` sets the file-position pointer to a specific location in the file relative to the beginning of the file, and `RandomAccessAccountRecord` method `write` outputs the data at the current position in the file. The program assumes that the user does not enter duplicate account numbers.

72 accountNumber = input.nextInt(); // read account number
73 firstName = input.next(); // read first name
74 lastName = input.next(); // read last name
75 balance = input.nextDouble(); // read balance
76
77 if (accountNumber > 0 && accountNumber <= NUMBER_RECORDS)
78 {
79 record.setAccount(accountNumber);
80 record.setFirstName(firstName);
81 record.setLastName(lastName);
82 record.setBalance(balance);
83
84 output.seek((accountNumber - 1) * // position to proper
85 RandomAccessAccountRecord.SIZE); // location for file
86 record.write(output);
87 } // end if
88 else
89 System.out.println("Account must be between 0 and 100.");
90 } // end try
91 catch (IOException ioException)
92 {
93 System.err.println("Error writing to file.");
94 return;
95 } // end catch
96 catch (NoSuchElementException elementException)
97 {
98 System.err.println("Invalid input. Please try again.");
99 input.nextLine(); // discard input so user can try again
100 } // end catch
101
102 System.out.printf("%s %s\n%s", "Enter account number (1-100)",
103 "first name, last name and balance.", "? ");
104 } // end while
105 } // end method addRecords
106 } // end class WriteRandomFile

```

Figure 14.27. Testing class **WriteRandomFile**.

(This item is displayed on page 715 in the print version)

```

1 // Fig. 14.27: WriteRandomFileTest.java
2 // This program tests class WriteRandomFile.
3
4 public class WriteRandomFileTest
5 {
6 public static void main(String args[])
7 {
8 WriteRandomFile application = new WriteRandomFile();
9 application.openFile();
10 application.addRecords();
11 application.closeFile();
12 } // end main
13 } // end class WriteRandomFileTest

```

To terminate input, type the end-of-file indicator when you are prompted to enter input.  
On UNIX/Linux/Mac OS X type <ctrl> d then press Enter  
On Windows type <ctrl> z then press Enter

```

Enter account number (1-100), first name, last name and balance.
? 37 Doug Barker 0.00
Enter account number (1-100), first name, last name and balance.
? 29 Nancy Brown -24.54
Enter account number (1-100), first name, last name and balance.
? 96 Sam Stone 34.98
Enter account number (1-100), first name, last name and balance.
? 88 Dave Smith 258.34
Enter account number (1-100), first name, last name and balance.
? 33 Stacey Dunn 314.33
Enter account number (1-100), first name, last name and balance.
? ^Z

```

The user enters values for the account number, first name, last name and balance. After each record is entered, the program stores the data in `RandomAccessAccountRecord` object `record` (lines 7982 of [Figure 14.26](#)) and calls `record`'s `write` method to output the data (line 86).

Lines 8485 call `RandomAccessFile` method `seek` to position the file-position pointer for object `output` to the byte location calculated by `( accountNumber - 1 ) * RandomAccessAccountRecord. SIZE`. Account numbers in this program are in the range 1100. We subtract one from the account number when calculating the byte location of the record. Thus, for record one, the file-position pointer is set to byte zero of the file. For record 100, the file-position pointer is set to skip the first 99 records in the file.

### 14.7.3. Reading Data Sequentially from a Random-Access File

In the preceding sections, we created a random-access file and wrote data to it. In this section, we develop a program ([Fig. 14.28](#)[Fig. 14.29](#)) that opens a `RandomAccessFile` for reading with the `"r"` file-open mode (line 19 of [Fig. 14.28](#)), reads through the file sequentially and displays only those records containing data.

The program produces an additional benefit. See whether you can determine what it is we reveal it at the end of this section.

Figure 14.28. Reading data sequentially from a random-access file.

(This item is displayed on pages 716 - 717 in the print version)

```

## Good Programming Practice 14.1

*Open a file with the "r" file-open mode for input if the contents should not be modified. This practice prevents unintentional modification of the file's contents. This is another example of the principle of least privilege.*

The program reads records by invoking method `readRecords` (lines 2859). This method invokes class `RandomAccessAccountRecord`'s read method (line 41) to read one record's data into `RandomAccessAccountRecord` object `record`. Method `readRecords` reads from the file using two loops. The outer loop, a `while` statement, loops until an attempt is made to read past the end of the file. The inner loop, a `do...while` statement, is used to read records until one is encountered with a nonzero account number (zero is the account number for empty records). At this point, the record is displayed. When all the records have been read, the file is closed and the program terminates. [Figure 14.29](#) contains method `main` and begins the execution of the program. Lines 911 open the file, call method `readRecords` and close the file.

---

[Page 717]

---

[Page 718]

---

What about that additional benefit we promised? If you examine the output, you will notice that the records are displayed in sorted order (by account number)! This ordering is a simple consequence of the way we stored these records in the file, using direct-access techniques. Sorting with direct-access techniques is blazingly fast. The speed is achieved by making the file large enough to hold every possible record that might be created, which enables the program to insert a record between other records without having to reorganize the file. This configuration, of course, means that the file could be sparsely occupied most of the time, a waste of storage. So this situation is another example of the space/time trade-off. By using large amounts of space, we are able to develop a much faster sorting algorithm.

### 14.7.4. Case Study: A Transaction-Processing Program

We now present a substantial transaction-processing program ([Fig. 14.33](#)[Fig. 14.36](#)), using a random-access file to achieve instant-access processing. The program maintains a bank's account information; it displays existing accounts, updates accounts, adds new accounts and deletes accounts. We assume that the program in [Fig. 14.24](#)[Fig. 14.25](#) has been executed to create a file, and that the program in [Fig. 14.26](#)[Fig. 14.27](#) has been executed to insert initial data. The techniques used in this example were presented in the earlier `RandomAccessFile` examples.

The program has five options. Option 1 displays a list of all the accounts in the file, using the same techniques as in the preceding section. Choosing option 1 displays the information in [Fig. 14.30](#).

Figure 14.30. Transaction processor displaying records.

| Account | First Name | Last Name | Balance |
|---------|------------|-----------|---------|
| 29      | Nancy      | Brown     | -24.54  |
| 33      | Stacey     | Dunn      | 314.33  |
| 37      | Doug       | Barker    | 0.00    |
| 88      | Dave       | Smith     | 258.34  |
| 96      | Sam        | Stone     | 34.98   |

Option 2 is used to update an account. The application will only update an existing record, so the function first checks to see whether the record specified by the user is empty. The record is read from the file, then the account number is compared to 0. If it is 0, the record contains no information, and a message is printed stating that the record is empty. Then, the menu choices are displayed. If the record contains information, the record's current information is displayed first. The user is then prompted for a change in the balance (either a charge or a payment), and the updated record is displayed. A typical output for option 2 is shown in [Fig. 14.31](#).

Figure 14.31. Transaction processor updating a record.

(This item is displayed on page 719 in the print version)

```

Enter account to update (1 - 100): 37
37 Doug Barker 0.00

Enter charge (+) or payment (-): +87.99
37 Doug Barker 87.99

```

Option 3 is used to add a new account to the file. The user is prompted to enter information for a new record. If the user enters an account number for an existing account, an error message is displayed indicating that the record already contains information, and the menu choices are printed again. If the account number entered does not correspond to an existing record (and all the data entered is valid), the new record is created and stored in the file. This code for this option uses the same process to add a new account as does the program in [Fig. 14.26](#)[Fig. 14.27](#). A typical output for option 3 is shown in [Fig. 14.32](#).

Figure 14.32. Transaction processor inserting a record.

```
Enter account number, first name, last name and balance.
(Account number must be 1 - 100)
? 22 Sarah Johnston 247.45
```

Option 4 is used to delete a record from the file. Deletion is accomplished by asking the user for the account number and reinitializing the record (i.e., writing a blank record in its place). If the account contains no information, `deleteRecord` displays an error message stating that the account does not exist. Option 5 terminates program execution. The program is shown in [Fig. 14.33](#)[Fig. 14.36](#). [Figure 14.33](#) defines the `enum` type for the user's options. The options are listed in lines 711.

Figure 14.33. Transaction processor's menu options.

```
1 // Fig. 14.33: MenuOption.java
2 // Defines an enum type for the credit inquiry program's options.
3
4 public enum MenuOption
5 {
6 // declare contents of enum type
7 PRINT(1),
8 UPDATE(2),
9 NEW(3),
10 DELETE(4),
11 END(5);
12
13 private final int value; // current menu option
14
15 MenuOption(int valueOption)
16 {
17 value = valueOption;
18 } // end MenuOptions enum constructor
19
20 public int getValue()
21 {
22 return value;
23 } // end method getValue
24 } // end enum MenuOption
```

Class `FileEditor` ([Fig. 14.34](#)) declares methods for manipulating records in a random-access file. This class uses all the techniques shown in the earlier examples. Method `getrecord` (lines 3145) reads the record with the given account number and stores its information in a `RandomAccessAccountRecord` object. Method `updateRecord` (lines 4864) modifies the record with the given account number, as long as the account number corresponds to a non-empty record. Method `newRecord` (lines 6783) adds a new record to the file using the provided account number, first name, last name and balance. Method `deleteRecord` (lines 86100) deletes the record with the given account number from the file, provided that the specified account exists. Method `readRecords` (lines 103136) displays all the currently existing records in the file.

173 while (choice != MenuOption.END)
174 {
175 performAction (choice);
176 choice = enterChoice();
177 } // end while
178
179 closeFile();
180 } // end method processRequests
181 } // end class TransactionProcessor

```

Figure 14.36. Testing class **transactionProcessor**.

(This item is displayed on page 726 in the print version)

```

1 // Fig. 14.36: TransactionProcessorTest.java
2 // Testing the transaction processor.
3
4 public class TransactionProcessorTest
5 {
6 public static void main(String args[])
7 {
8 TransactionProcessor application = new TransactionProcessor();
9 application.processRequests();
10 } // end main
11 } // end class TransactionProcessorTest

```

Method `processRequests` (lines 166180) processes the choices entered by the user. If the user does not enter 5 (which ends the program), method `performAction` (lines 51140) is called. This method inputs information from the user and sends it to the appropriate method of class `FileEditor` ([Fig. 14.34](#)), which encapsulates the file-processing operations in this example. The method to call is determined by `performAction`'s `MenuOption` argument. Each option is handled in the `switch` statement of lines 61121. Method `performAction` also handles any exceptions that might be thrown from `FileEditor`'s methods.

## 14.8. Additional java.io Classes

We now introduce you to other useful classes in the `java.io` package. We overview additional interfaces and classes for byte-based input and output streams, and character-based input and output streams.

### Interfaces and Classes for Byte-Based Input and Output

`InputStream` and `OutputStream` (subclasses of `Object`) are `abstract` classes that declare methods for performing byte-based input and output, respectively. We used concrete classes `FileInputStream` (a subclass of `InputStream`) and `FileOutputStream` (a subclass of `OutputStream`) to manipulate files in this chapter.

`Pipes` are synchronized communication channels between threads. We discuss threads in [Chapter 23](#), Multithreading. Java provides `PipedOutputStream` (a subclass of `OutputStream`) and `PipedInputStream` (a subclass of `InputStream`) to establish pipes between two threads in a program. One thread sends data to another by writing to a `PipedOutputStream`. The target thread reads information from the pipe via a `PipedInputStream`.

A `FilterInputStream` filters an `InputStream`, and a `FilterOutputStream` filters an `OutputStream`. Filtering means simply that the filter stream provides additional functionality, such as aggregating data bytes into meaningful primitive-type units. `FilterInputStream` and `FilterOutputStream` are `abstract` classes, so some of their filtering capabilities are provided by their concrete subclasses.

A `PrintStream` (a subclass of `FilterOutputStream`) performs text output to the specified stream. Actually, we have been using `PrintStream` output throughout the text to this point. `System.out` and `System.err` are `PrintStream` objects.

Reading data as raw bytes is fast, but crude. Usually, programs read data as aggregates of bytes that form `ints`, `floats`, `doubles` and so on. Java programs can use several classes to input and output data in aggregate form.

Interface `DataInput` (discussed in [Section 14.7.1](#)) describes methods for reading primitive types from an input stream. Classes `DataInputStream` and `RandomAccessFile` each implement this interface to read sets of bytes and view them as primitive-type values. Interface `DataInput` includes methods `readLine` (for `byte` arrays), `readBoolean`, `readByte`, `readChar`, `readDouble`, `readFloat`, `readFully` (for `byte` arrays), `readInt`, `readLong`, `readShort`, `readUnsignedByte`, `readUnsignedShort`, `readUTF` (for reading Unicode characters encoded by Java) we discuss UTF encoding in [Appendix F](#), Unicode®) and `skipBytes`.

Interface `DataOutput` (discussed in [Section 14.7.1](#)) describes a set of methods for writing primitive types to an output stream. Classes `DataOutputStream` (a subclass of `FilterOutputStream`) and `RandomAccessFile` each implement this interface to write primitive-type values as bytes. Interface `DataOutput` includes overloaded versions of method `write` (for a `byte` or for a `byte` array) and methods `writeBoolean`, `writeByte`, `writeBytes`, `writeChar`, `writeChars` (for Unicode `Strings`), `writeDouble`, `writeFloat`, `writeInt`, `writeLong`, `writeShort` and `writeUTF` (to output text modified for Unicode).

**Buffering** is an I/O-performance-enhancement technique. With a `BufferedOutputStream` (a subclass of class `FilterOutputStream`), each output statement does not necessarily result in an actual physical transfer of data to the output device (which is a slow operation compared to processor and main memory speeds). Rather, each output operation is directed to a region in memory called a `buffer` that is large enough to hold the data of many output operations. Then, actual transfer to the output device is performed in one large **physical output operation** each time the buffer fills. The output operations directed to the output buffer in memory are often called **logical output operations**. With a `BufferedOutputStream`, a partially filled buffer can be forced out to the device at any time by invoking the stream object's `flush` method.

Using buffering can greatly increase the efficiency of an application. Typical I/O operations are extremely slow compared with the speed of accessing computer memory. Buffering reduces the number of I/O operations by first combining smaller outputs together in memory. The number of actual physical I/O operations is small compared with the number of I/O requests issued by the program. Thus, the program that is using buffering is more efficient.

### Performance Tip 14.1

*Buffered I/O can yield significant performance improvements over unbuffered I/O.*

With a **BufferedInputStream** (a subclass of class **FilterInputStream**), many "logical" chunks of data from a file are read as one large **physical input operation** into a memory buffer. As a program requests each new chunk of data, it is taken from the buffer. (This procedure is sometimes referred to as a **logical input operation**.) When the buffer is empty, the next actual physical input operation from the input device is performed to read in the next group of "logical" chunks of data. Thus, the number of actual physical input operations is small compared with the number of read requests issued by the program.

Earlier in the chapter we used class **StringBuffer**, which allows us to dynamically manipulate strings. It is important to note that class **StringBuffer** can be used to buffer output that will be displayed later to the screen or in a **JTextArea**. This increases the efficiency of a program just as with buffering, it is much faster to first combine all the program's output in a **StringBuffer** object and display the final output to a **JTextArea** or the screen, then to continually add text to a **JTextArea** or the screen. We discuss class **StringBuffer** in more detail in [Chapter 29](#), Strings, Characters and Regular Expressions.

Java stream I/O includes capabilities for inputting from **byte** arrays in memory and outputting to **byte** arrays in memory. A **ByteArrayInputStream** (a subclass of **InputStream**) reads from a **byte** array in memory. A **ByteArrayOutputStream** (a subclass of **OutputStream**) outputs to a **byte** array in memory. One use of **byte**-array I/O is data validation. A program can input an entire line at a time from the input stream into a **byte** array. Then a validation routine can scrutinize the contents of the **byte** array and correct the data if necessary. Finally, the program can proceed to input from the **byte** array, "knowing" that the input data is in the proper format. Outputting to a **byte** array is a nice way to take advantage of the powerful output-formatting capabilities of Java streams. For example, data can be stored in a **byte** array, using the same formatting that will be displayed at a later time, and the **byte** array can then be output to a disk file to preserve the screen image.

A **SequenceInputStream** (a subclass of **InputStream**) enables concatenation of several **InputStreams**, which means that the program sees the group as one continuous **InputStream**. When the program reaches the end of an input stream, that stream closes, and the next stream in the sequence opens.

## Interfaces and Classes for Character-Based Input and Output

In addition to the **byte**-based streams, Java provides the **Reader** and **Writer** abstract classes, which are Unicode two-byte, character-based streams. Most of the **byte**-based streams have corresponding character-based concrete **Reader** or **Writer** classes.

Classes **BufferedReader** (a subclass of abstract class **Reader**) and **BufferedWriter** (a subclass of abstract

class `Writer`) enable buffering for character-based streams. Remember that character-based streams use Unicode characters; such streams can process data in any language that the Unicode character set represents.

Classes `CharArrayReader` and `CharArrayWriter` read and write, respectively, a stream of characters to a character array. A `LineNumberReader` (a subclass of `BufferedReader`) is a buffered character stream that keeps track of the number of lines read (i.e., a newline, a return or a carriage-returnline-feed combination). Keeping track of line numbers can be useful if the program needs to inform the reader of an error on a specific line.

Class `FileReader` (a subclass of `InputStreamReader`) and class `FileWriter` (a subclass of `OutputStreamWriter`) read characters from and write characters to a file, respectively. Class `PipedReader` and class `PipedWriter` implement piped-character streams that can be used to transfer information between threads. Class `StringReader` and `StringWriter` read characters from and write characters to `Strings`, respectively. A `PrintWriter` writes characters to a stream.

[NEXT ▶](#)

## 14.9. Opening Files with `JFileChooser`

We conclude this chapter by introducing class `JFileChooser`. We use this class to display a dialog (known as the `JFileChooser` dialog) that enables users of our program to easily select files. To demonstrate the `JFileChooser` dialog, we enhance the example in [Section 14.4](#), as shown in [Fig. 14.37](#)[Fig. 14.38](#). The example now contains a graphical user interface, but still displays the same data as before. The constructor calls method `analyzePath` in line 34. This method then calls method `getFile` in line 68 to retrieve the `File` object.

Figure 14.37. Demonstrating `JFileChooser`.

(This item is displayed on pages 730 - 731 in the print version)

9 import javax.swing.JOptionPane;
10 import javax.swing.JScrollPane;
11 import javax.swing.JTextArea;
12 import javax.swing.JTextField;
13
14 public class FileDemonstration extends JFrame
15 {
16 private JTextArea outputArea; // used for output
17 private JScrollPane scrollPane; // used to provide scrolling to output
18
19 // set up GUI
20 public FileDemonstration()
21 {
22 super("Testing class File");
23
24 outputArea = new JTextArea();
25
26 // add outputArea to scrollPane
27 scrollPane = new JScrollPane(outputArea);
28
29 add(scrollPane, BorderLayout.CENTER); // add scrollPane to GUI
30
31 setSize(400, 400); // set GUI size
32 setVisible(true); // display GUI
33
34 analyzePath(); // create and analyze File object
35 } // end FileDemonstration constructor
36
37 // allow user to specify file name
38 private File getFile()
39 {
```

```

40 // display file dialog, so user can choose file to open
41 JFileChooser fileChooser = new JFileChooser();
42 fileChooser.setFileSelectionMode(
43 JFileChooser.FILES_AND_DIRECTORIES);
44
45 int result = fileChooser.showOpenDialog(this);
46
47 // if user clicked Cancel button on dialog, return
48 if (result == JFileChooser.CANCEL_OPTION)
49 System.exit(1);
50
51 File fileName = fileChooser.getSelectedFile(); // get selected file
52
53 // display error if invalid
54 if ((fileName == null) || (fileName.getName().equals("")))
55 {
56 JOptionPane.showMessageDialog(this, "Invalid File Name",
57 "Invalid File Name", JOptionPane.ERROR_MESSAGE);
58 System.exit(1);
59 } // end if
60
61 return fileName;
62 } // end method getFile
63
64 // display information about file user specifies
65 public void analyzePath()
66 {
67 // create File object based on user input
68 File name = getFile();
69
70 if (name.exists()) // if name exists, output information about it
71 {
72 // display file (or directory) information
73 outputArea.setText(String.format(
74 "%s\n%s\n%s\n%s\n%s\n%s\n%s\n%s\n%s\n%s",
75 name.getName(), " exists",
76 (name.isFile() ? "is a file" : "is not a file"),
77 (name.isDirectory() ? "is a directory" :
78 "is not a directory"),
79 (name.isAbsolute() ? "is absolute path" :
80 "is not absolute path"), "Last modified: ",
81 name.lastModified(), "Length: ", name.length(),
82 "Path: ", name.getPath(), "Absolute path: ",
83 name.getAbsolutePath(), "Parent: ", name.getParent()));
84
85 if (name.isDirectory()) // output directory listing
86 {
87 String directory[] = name.list();
88 outputArea.append("\n\nDirectory contents:\n");
89
90 for (String directoryName : directory)
91 outputArea.append(directoryName + "\n");
92 } // end else
93 } // end outer if
94 else // not file or directory, output error message
95 {
96 JOptionPane.showMessageDialog(this, name +
97 " does not exist.", "ERROR", JOptionPane.ERROR_MESSAGE);
98 } // end else
99 } // end method analyzePath
100 } // end class FileDemonstration

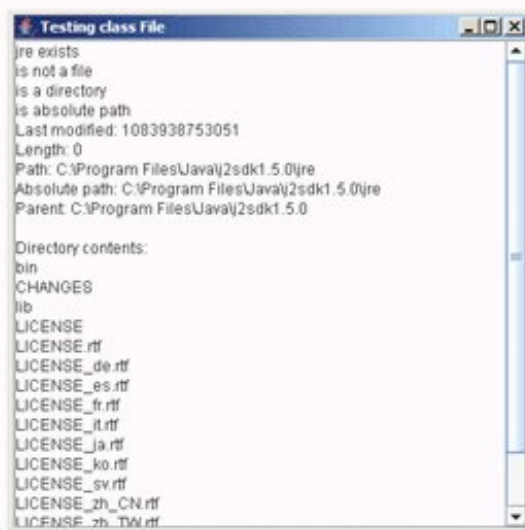

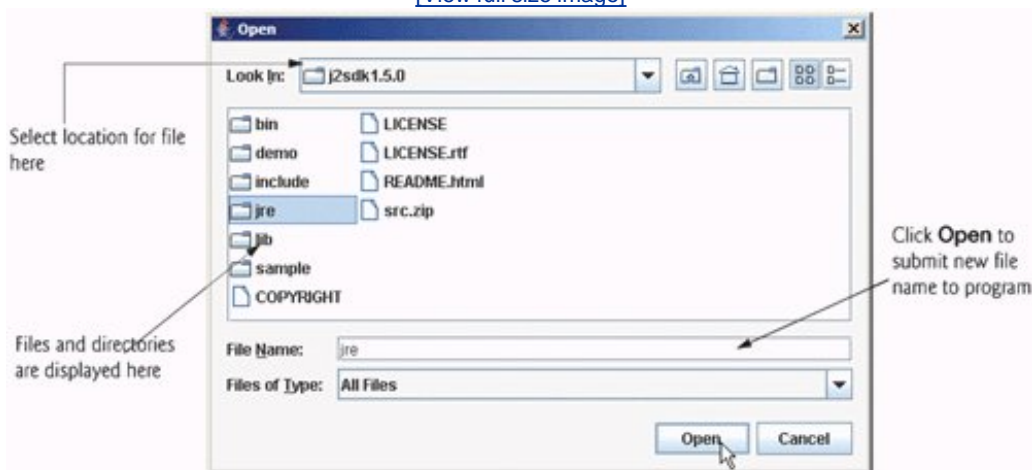

```

Figure 14.38. Testing class **FileDemonstration**.

(This item is displayed on page 732 in the print version)

```
1 // Fig. 14.38: FileDemonstrationTest.java
2 // Testing the FileDmonstration class.
3 import javax.swing.JFrame;
4
5 public class FileDemonstrationTest
6 {
7 public static void main(String args[])
8 {
9 FileDemonstration application = new FileDemonstration();
10 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 } // end main
12 } // end class FileDemonstrationTest
```

[\[View full size image\]](#)

Method `getFile` is defined in lines 3862 of [Fig. 14.37](#). Line 41 creates a `JFileChooser` and assigns its reference to `fileChooser`. Lines 4243 call method `setFileSelectionMode` to specify what the user can select from the `fileChooser`. For this program, we use `JFileChooser` static constant `FILES_AND_DIRECTORIES` to indicate that files and directories can be selected. Other static constants include `FILES_ONLY` and `DIRECTORIES_ONLY`.

Line 45 calls method `showOpenDialog` to display the `JFileChooser` dialog titled Open. Argument `this` specifies the `JFileChooser` dialog's parent window, which determines the position of the dialog on the screen. If `null` is passed, the dialog is displayed in the center of the screen otherwise, the dialog is centered over the application window (specified by the argument `this`). A `JFileChooser` dialog is a modal dialog that does not allow the user to interact with any other window in the program until the user closes the `JFileChooser` by clicking the Open or Cancel button. The user selects the drive, directory or file name, then clicks Open. Method `showOpenDialog` returns an integer specifying which button ( Open or Cancel) the user clicked to close the dialog. Line 48 tests whether the user clicked Cancel by comparing the result with static constant `CANCEL_OPTION`. If they are equal, the program terminates. Line 51 retrieves the file the user selected by calling `JFileChooser` method `getSelectedFile`. The program then displays information about the selected file or directory.

## 14.10. Wrap-Up

In this chapter, you learned how to use file processing to manipulate persistent data. You learned that data is stored in computers as `0s` and `1s`, and that combinations of these values are used to form bytes, fields, records and eventually files. You were given an overview of the differences between character-based and byte-based streams, as well as an introduction to several file-processing classes provided by the `java.io` package. You used class `File` to retrieve information about a file or directory. Next, you learned how to use sequential-access file processing to manipulate records that are stored in order by the record-key field. In that discussion, you learned the differences between text-file processing and object serialization, and used serialization to store and retrieve entire objects. You then learned how to use random-access files to instantly retrieve and manipulate fixed-length records. The chapter concluded with an overview of other classes provided by the `java.io` package, and a small example of using a `JFileChooser` dialog to allow users to easily select files from a GUI. In the next chapter, you will learn the concept of recursion methods that call themselves. Defining methods in this manner sometimes leads to more intuitive programs.

## Summary

- Data stored in variables and arrays is temporarythe data is lost when a local variable goes out of scope or when the program terminates. Computers use files for long-term retention of large amounts of data, even after the programs that created the data terminate.
- Persistent data maintained in files exists beyond the duration of program execution.
- Computers store files on secondary storage devices such as hard disks.
- The smallest data item in a computer can assume the value `0` or the value `1` and is called a bit. Ultimately, a computer processes all data items as combinations of zeros and ones.
- The computer's character set is the set of all characters used to write programs and represent data.
- Characters in Java are Unicode characters composed of two bytes, each composed of eight bits.
- Just as characters are composed of bits, fields are composed of characters or bytes. A field is a group of characters or bytes that conveys meaning.
- Data items processed by computers form a data hierarchy that becomes larger and more complex in structure as we progress from bits to characters to fields, and so on.
- Typically, several fields compose a record (implemented as a `class` in Java).
- A record is a group of related fields.
- A file is a group of related records.
- To facilitate the retrieval of specific records from a file, at least one field in each record is chosen as a record key. A record key identifies a record as belonging to a particular person or entity and is unique to each record.
- There are many ways to organize records in a file. The most common is called a sequential file, in which records are stored in order by the record-key field.
- A group of related files is often called a database. A collection of programs designed to create and manage databases is called a database management system (DBMS).
- Java views each file as a sequential stream of bytes.
- Every operating system provides a mechanism to determine the end of a file, such as an end-of-file marker or a count of the total bytes in the file that is recorded in a system-maintained administrative data structure.

- Byte-based streams represent data in binary format.
- Character-based streams represent data as sequences of characters.
- Files that are created using byte-based streams are binary files. Files created using character-based streams are text files. Text files can be read by text editors, whereas binary files are read by a program that converts the data to a human-readable format.
- Java also can associate streams with different devices. Three stream objects are associated with

devices when a Java program begins executing `System.in`, `System.out` and `System.err`.

- The `java.io` package includes definitions for stream classes, such as `FileInputStream` (for byte-based input from a file), `FileOutputStream` (for byte-based output to a file), `FileReader` (for character-based input from a file) and `FileWriter` (for character-based output to a file). Files are opened by creating objects of these stream classes.
- Class `File` is used to obtain information about files and directories.
- Character-based input and output can be performed with classes `Scanner` and `Formatter`.
- Class `Formatter` enables formatted data to be output to the screen or to a file in a manner similar to `System.out.printf`.
- A file or directory's path specifies its location on disk.
- An absolute path contains all the directories, starting with the root directory, that lead to a specific file or directory. Every file or directory on a disk drive has the same root directory in its path.
- A relative path normally starts from the directory in which the application began executing.
- A separator character is used to separate directories and files in the path.
- Java imposes no structure on a file; notions such as a record do not exist as part of the Java language. The programmer must structure files to meet an application's requirements.
- To retrieve data sequentially from a file, programs normally start reading from the beginning of the file and read all the data consecutively until the desired information is found.
- Data in many sequential files cannot be modified without the risk of destroying other data in the file. Therefore, records in a sequential-access file are not usually updated in place. Instead, the entire file is usually rewritten.
- Java provides a mechanism called object serialization that enables entire objects to be written to or read from a stream.
- A serialized object is an object represented as a sequence of bytes that includes the object's data as well as information about the object's type and the types of data stored in the object.
- After a serialized object has been written into a file, it can be read from the file and deserialized; that is, the type information and bytes that represent the object and its data can be used to recreate the object in memory.
- Classes `ObjectInputStream` and `ObjectOutputStream`, which respectively implement the `ObjectInput` and `ObjectOutput` interfaces, enable entire objects to be read from or written to a stream (possibly a file).
- Only classes that implement interface `Serializable` can be serialized and deserialized with `ObjectOutputStreams` and `ObjectInputStreams`.
- The `ObjectOutput` interface contains method `writeObject`, which takes an `Object` that implements interface `Serializable` as an argument and writes its information to an `OutputStream`.
- The `ObjectInput` interface contains method `readObject`, which reads and returns a reference to an `Object` from an `InputStream`. After an object has been read, its reference can be cast to the object's actual type.

- Instant record access is possible with random-access files and with databases. A program can access individual records of a random-access file directly (and quickly) without searching through other records. Random-access files are sometimes called direct-access files.

- Several techniques can be used to create random-access files. Perhaps the simplest is to require that all the records in a file be of the same fixed length.
- Using fixed-length records makes it easy for a program to calculate (as a function of the record size and the record key) the exact location of any record relative to the beginning of the file.
- When a program associates an object of class `RandomAccessFile` with a file, the program reads or writes data, beginning at the location in the file specified by the file-position pointer, and manipulates all the data as primitive types.
- `RandomAccessFile` method `seek` positions to the exact location in the file at which a record of information is stored. Method `seek` sets the file-position pointer to a specific location in the file relative to the beginning of the file.
- Buffering is an I/O-performance-enhancement technique. With a `BufferedOutputStream`, each output statement does not necessarily result in an actual physical transfer of data to the output device. Rather, each output operation is directed to a region in memory called a buffer that is large enough to hold the data of many output operations. Actual transfer to the output device is then performed in one large physical output operation each time the buffer fills.
- With a `BufferedInputStream`, many "logical" chunks of data from a file are read as one large physical input operation into a memory buffer. As a program requests each new chunk of data, it is taken from the buffer. When the buffer is empty, the next actual physical input operation from the input device is performed to read in the next group of "logical" chunks of data.
- Class `JFileChooser` is used to display a dialog that enables users of a program to easily select files from a GUI.

## Self-Review Exercises

14.1 Fill in the blanks in each of the following statements:

- a. Ultimately, all data items processed by a computer are reduced to combinations of \_\_\_\_\_ and \_\_\_\_\_.
- b. The smallest data item a computer can process is called a(n)\_\_\_\_\_.
- c. A(n) \_\_\_\_\_ can sometimes be viewed as a group of related records.
- d. Digits, letters and special symbols are referred to as \_\_\_\_\_.
- e. A group of related files is called a \_\_\_\_\_.
- f. Object \_\_\_\_\_ normally enables a program to output error messages to the screen.
- g. `RandomAccessFile` method \_\_\_\_\_ reads an integer from the specified stream.
- h. `RandomAccessFile` method \_\_\_\_\_ sets the file-position pointer to a specific location in a file for input or output.

14.2 Determine which of the following statements are *true* and which are *false*. If *false*, explain why.

- a. The programmer must explicitly create the stream objects `System.in`, `System.out` and `System.err`.
- b. When reading data from a file using class `Scanner`, if the programmer wishes to read data in the file multiple times, the file must be closed and reopened to read from the beginning of the file. This moves the file-position pointer back to the beginning of the file.
- c. Method `exists` of class `File` returns `TRUE` if the name specified as the argument to the `File` constructor is a file or directory in the specified path.
- d. It is not necessary to search all the records in a random-access file to find a record.
- e. Binary files are human readable.
- f. An absolute path contains all the directories, starting with the root directory, that lead to a specific file or directory.
- g. Class `Formatter` contains method `printf`, which enables formatted data to be output to the screen or to a file.

14.3 Complete the following tasks, assuming that each applies to the same program:

- a. Write a statement that opens file `"oldmast.txt"` for input use `Scanner` variable `inOldMaster`.
- b. Write a statement that opens file `"trans.txt"` for input use `Scanner` variable

`inTransaction`.

- c. Write a statement that opens file `"newmast.txt"` for output (and creation) use `formatter` variable `outNewMaster`.
- d. Write the statements needed to read a record from the file `"oldmast.txt"`. The data read should be used to create an object of class `AccountRecord` use `Scanner` variable `inOldMaster`. Assume that class `AccountRecord` is the same as the `AccountRecord` class in [Fig. 14.6](#).
- e. Write the statements needed to read a record from the file `"trans.txt"`. The record is an object of class `transactionRecord` use `Scanner` variable `inTransaction`. Assume that class `transactionRecord` contains method `setAccount` (which takes an `int`) to set the account number and method `setAmount` (which takes a `double`) to set the amount of the transaction.
- f. Write a statement that outputs a record to the file `"newmast.txt"`. The record is an object of type `AccountRecord` use `Formatter` variable `outNewMaster`.

**14.4** Complete the following tasks, assuming that each applies to the same program:

- a. Write a statement that opens file `"oldmast.ser"` for input use `ObjectInputStream` variable `inOldMaster` to wrap a `FileInputStream` object.

---

[Page 738]

- b. Write a statement that opens file `"trans.ser"` for input use `ObjectInputStream` variable `inTransaction` to wrap a `FileInputStream` object.
- c. Write a statement that opens file `"newmast.ser"` for output (and creation) use `ObjectOutputStream` variable `outNewMaster` to wrap a `FileOutputStream`.
- d. Write a statement that reads a record from the file `"oldmast.ser"`. The record is an object of class `AccountRecordSerializable` use `ObjectInputStream` variable `inOldMaster`. Assume class `AccountRecordSerializable` is the same as the `AccountRecordSerializable` class in [Fig. 14.17](#).
- e. Write a statement that reads a record from the file `"trans.ser"`. The record is an object of class `transactionRecord` use `ObjectInputStream` variable `inTransaction`.
- f. Write a statement that outputs a record to the file `"newmast.ser"`. The record is an object of type `AccountRecordSerializable` use `ObjectOutputStream` variable `outNewMaster`.

**14.5** Find the error in each block of code and show how to correct it.

- a. Assume that `account`, `company` and `amount` are declared.

```
ObjectOutputStream outputStream;

outputStream.writeInt(account);
outputStream.writeChars(company);
outputStream.writeDouble(amount);
```

- b. The following statements should read a record from the file `"payables.txt"`. The `Scanner` variable `inPayable` should be used to refer to this file.

```
Scanner inPayable = new Scanner(new File("payables.txt"));
PayablesRecord record = (PayablesRecord) inPayable.readObject();
```

[< PREV](#)[NEXT >](#)

## Answers to Self-Review Exercises

[14.1](#) a) ones, zeros. b) bit. c) file. d) characters. e) database. f) `System.err`. g) `readInt`. h) `seek`.

### [14.2](#)

- a. False. These three streams are created for the programmer when a Java application begins executing.
- b. True.
- c. True.
- d. True.
- e. False. Text files are human readable.
- f. True.
- g. False. Class `Formatter` contains method `format`, which enables formatted data to be output to the screen or to a file.

### [14.3](#)

- a. 

```
Scanner inOldMaster = new Scanner(new File ("oldmast.txt"));
```
- b. 

```
Scanner inTransaction = new Scanner(new File("trans.txt"));
```
- c. 

```
Formatter outNewMaster = new Formatter("newmast.txt");
```
- d. 

```
AccountRecord account = new AccountRecord();
 account.setAccount(inOldMaster.nextInt());
 account.setFirstName(inOldMaster.next());
 account.setLastName(inOldMaster.next());
 account.setBalance(inOldMaster.nextDouble());
```
- e. 

```
TransactionRecord transaction = new Transaction();
 transaction.setAccount(inTransaction.nextInt());
 transaction.setAmount(inTransaction.nextDouble());
```

```
f. outNewMaster.format("%d %s %s %.2f\n",
 account.getAccount(), account.getFirstName(),
 account.getLastName(), account.getBalance());
```

## 14.4

```
a. ObjectInputStream inOldMaster = new ObjectInputStream(
 new FileInputStream("oldmast.ser"));

b. ObjectInputStream inTransaction = new ObjectInputStream(
 new FileInputStream("trans.ser"));

c. ObjectOutputStream outNewMaster = new ObjectOutputStream(
 new FileOutputStream("newmast.ser"));

d. accountRecord = (AccountRecordSerializable) inOldMaster.readObject();

e. transactionRecord = (TransactionRecord) inTransaction.readObject();

f. outNewMaster.writeObject(newAccountRecord);
```

## 14.5

a. Error: The file has not been opened before the attempt is made to output data to the stream.

Correction: Open a file for output by creating a new `ObjectOutputStream` object that wraps a `FileOutputStream` object.

b. Error: This example uses text files with a `Scanner`, there is no object serialization. As a result, method `readObject` cannot be used to read that data from the file. Each piece of data must be read separately, then used to create a `PayablesRecord` object.

Correction: Use `methods` of `inPayable` to read each piece of the `PayablesRecord` object.

## Exercises

14.6 Fill in the blanks in each of the following statements:

- a. Computers store large amounts of data on secondary storage devices as \_\_\_\_\_.
- b. A(n) \_\_\_\_\_ is composed of several fields.
- c. To facilitate the retrieval of specific records from a file, one field in each record is chosen as a(n) \_\_\_\_\_.
- d. Files that are created using byte-based streams are referred to as \_\_\_\_\_ files, while files created using character-based streams are referred to as \_\_\_\_\_ files.
- e. The standard stream objects are \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.

14.7 Determine which of the following statements are *true* and which are *false*. If *false*, explain why.

- a. The impressive functions performed by computers essentially involve the manipulation of zeros and ones.
- b. People specify programs and data items as characters. Computers then manipulate and process these characters as groups of zeros and ones.
- c. Data items represented in computers form a data hierarchy in which data items become larger and more complex as we progress from fields to characters to bits and so on.
- d. A record key identifies a record as belonging to a particular field.
- e. Companies store all their information in a single file to facilitate computer processing of the information. When a program creates a file, the file is retained by the computer for future reference.

14.8 (*File Matching*) Self-Review [Exercise 14.3](#) asks the reader to write a series of single statements. Actually, these statements form the core of an important type of file-processing program, namely, a file-matching program. In commercial data processing, it is common to have several files in each application system. In an accounts receivable system, for example, there is generally a master file containing detailed information about each customer, such as the customer's name, address, telephone number, outstanding balance, credit limit, discount terms, contract arrangements and possibly a condensed history of recent purchases and cash payments.

As transactions occur (i.e., sales are made and payments arrive in the mail), information about them is entered into a file. At the end of each business period (a month for some companies, a week for others, and a day in some cases), the file of transactions (called "`trans.txt`") is applied to the master file (called "`oldmast.txt`") to update each account's purchase and payment record. During an update, the master file is rewritten as the file

"newmast.txt", which is then used at the end of the next business period to begin the updating process again.

File-matching programs must deal with certain problems that do not arise in single-file programs. For example, a match does not always occur. If a customer on the master file has not made any purchases or cash payments in the current business period, no record for this customer will appear on the transaction file. Similarly, a customer who did make some purchases or cash payments could have just moved to this community, and if so, the company may not have had a chance to create a master record for this customer.

Write a complete file-matching accounts receivable program. Use the account number on each file as the record key for matching purposes. Assume that each file is a sequential text file with records stored in increasing account-number order.

- Define class `TRansactionRecord`. Objects of this class contain an account number and amount for the transaction. Provide methods to modify and retrieve these values.
- Modify class `AccountRecord` in [Fig. 14.6](#) to include method `combine`, which takes a `transactionRecord` object and combines the balance of the `AccountRecord` object and the amount value of the `transactionRecord` object.
- Write a program to create data for testing the program. Use the sample account data in [Fig. 14.39](#) and [Fig. 14.40](#). Run the program to create the files `TRans.txt` and `oldmast.txt`, to be used by your file-matching program.

Figure 14.39. Sample data for master file.

| Master file<br>Account<br>number | Name       | Balance |
|----------------------------------|------------|---------|
| 100                              | Alan Jones | 348.17  |
| 300                              | Mary Smith | 27.19   |
| 500                              | Sam Sharp  | 0.00    |
| 700                              | Suzy Green | 14.22   |

Figure 14.40. Sample data for transaction file.

| Transaction file<br>Account number | Transaction amount |
|------------------------------------|--------------------|
| 100                                | 27.14              |
| 300                                | 62.11              |
| 400                                | 100.56             |
| 900                                | 82.17              |

- d. Create class `FileMatch` to perform the file-matching functionality. The class should contain methods that read `oldmast.txt` and `TRans.txt`. When a match occurs (i.e., records with the same account number appear in both the master file and the transaction file), add the dollar amount in the transaction record to the current balance in the master record, and write the `"newmast.txt"` record. (Assume that purchases are indicated by positive amounts in the transaction file and payments by negative amounts.) When there is a master record for a particular account, but no corresponding transaction record, merely write the master record to `"newmast.txt"`. When there is a transaction record, but no corresponding master record, print to a log file the message `"Unmatched transaction record for account number..."` (fill in the account number from the transaction record). The log file should be a text file named `"log.txt"`.

---

[Page 741]

- 14.9 (*File Matching with Multiple Transactions*) It is possible (and actually common) to have several transaction records with the same record key. This situation occurs, for example, when a customer makes several purchases and cash payments during a business period. Rewrite your accounts receivable file-matching program from [Exercise 14.8](#) to provide for the possibility of handling several transaction records with the same record key. Modify the test data of `CreateData.java` to include the additional transaction records in [Fig. 14.41](#).

Figure 14.41. Additional transaction records.

| Account number | Dollar amount |
|----------------|---------------|
| 300            | 83.89         |
| 700            | 80.78         |
| 700            | 1.53          |

- 14.10 (*File Matching with Object Serialization*) Recreate your solution for [Exercise 14.9](#) using object serialization. Use the statements from [Exercise 14.4](#) as your basis for this program. You may want to create applications to read the data stored in the `.ser` file the code in [Section 14.7.3](#) can be modified for this purpose.
- 14.11 (*Hardware Store Inventory*) You are the owner of a hardware store and need to keep an inventory that can tell you what different tools you stock, how many of each you have on hand and the cost of each one. Write a program that initializes the random-access file `"hardware.dat"` to 100 empty records and lets you input the data concerning each tool, list all your tools, delete a record for a tool that you no longer have and update *any* information in the file. The tool identification number should be the record number. Use the information in [Fig. 14.42](#) to start your file.

Figure 14.42. Data for [Exercise 14.11](#).

| Record number | Tool name | Quantity | Cost  |
|---------------|-----------|----------|-------|
| 3             | Sander    | 18       | 35.99 |

| Record number | Tool name    | Quantity | Cost  |
|---------------|--------------|----------|-------|
| 19            | Hammer       | 128      | 10.00 |
| 26            | Jigsaw       | 16       | 14.25 |
| 39            | Mower        | 10       | 79.50 |
| 56            | Saw          | 8        | 89.99 |
| 76            | Screwdriver  | 236      | 4.99  |
| 81            | Sledgehammer | 32       | 19.75 |
| 88            | Wrench       | 65       | 6.48  |

---

[Page 742]

- 14.12 *(Telephone-Number Word Generator)* Standard telephone keypads contain the digits zero through nine. The numbers two through nine each have three letters associated with them ([Fig. 14.43](#)). Many people find it difficult to memorize phone numbers, so they use the correspondence between digits and letters to develop seven-letter words that correspond to their phone numbers. For example, a person whose telephone number is 686-2377 might use the correspondence indicated in [Fig. 14.43](#) to develop the seven-letter word "NUMBERS." Every seven-letter word corresponds to exactly one seven-digit telephone number. A restaurant wishing to increase its takeout business could surely do so with the number 825-3688 (i.e., "TAKEOUT").

Figure  
14.43.  
Telephone  
keypad  
digits and  
letters.

| Digit | Letters |
|-------|---------|
| 2     | A B C   |
| 3     | D E F   |
| 4     | G H I   |
| 5     | J K L   |
| 6     | M N O   |
| 7     | P R S   |
| 8     | T U V   |
| 9     | W X Y   |

Every seven-letter phone number corresponds to many different seven-letter words. Unfortunately, most of these words represent unrecognizable juxtapositions of letters. It is possible, however, that the owner of a barbershop would be pleased to know that the shop's

telephone number, 424-7288, corresponds to "HAIRCUT." The owner of a liquor store would, no doubt, be delighted to find that the store's number, 233-7226, corresponds to "BEERCAN." A veterinarian with the phone number 738-2273 would be pleased to know that the number corresponds to the letters "PETCARE." An automotive dealership would be pleased to know that the dealership number, 639-2277, corresponds to "NEWCARS."

Write a program that, given a seven-digit number, uses a `PrintStream` object to write to a file every possible seven-letter word combination corresponding to that number. There are 2,187 ( $3^7$ ) such combinations. Avoid phone numbers with the digits 0 and 1.

- 14.13 *(Student Poll)* [Figure 7.8](#) contains an array of survey responses that is hard coded into the program. Suppose we wish to process survey results that are stored in a file. This exercise requires two separate programs. First, create an application that prompts the user for survey responses and outputs each response to a file. Use a `Formatter` to create a file called `numbers.txt`. Each integer should be written using method `format`. Then modify the program in [Fig. 7.8](#) to read the survey responses from `numbers.txt`. The responses should be read from the file by using a `Scanner`. Method `nextInt` should be used to input one integer at a time from the file. The program should continue to read responses until it reaches the end of file. The results should be output to the text file `"output.txt"`.
- 14.14 Modify [Exercise 11.18](#) to allow the user to save a drawing into a file or load a prior drawing from a file using object serialization. Add buttons Load (to read objects from a file), Save (to write objects to a file) and Generate Shapes (to display a random set of shapes on the screen). Use an `ObjectOutputStream` to write to the file and an `ObjectInputStream` to read from the file. Write the array of `MyShape` objects using method `writeObject` (class `ObjectOutputStream`), and read the array using method `readObject` (`ObjectInputStream`). Note that the object-serialization mechanism can read or write entire arrays; it is not necessary to manipulate each element of the array of `MyShape` objects individually. It is simply required that all the shapes be `Serializable`. For both the Load and Save buttons, use a `JFileChooser` to allow the user to select the file in which the shapes will be stored or from which they will be read. When the user first runs the program, no shapes should be displayed on the screen. The

## OBJECTIVES

In this chapter you will learn:

- The concept of recursion.
- How to write and use recursive methods.
- How to determine the base case and recursion step in a recursive algorithm.
- How recursive method calls are handled by the system.
- The differences between recursion and iteration, and when it is appropriate to use each.

## 15.1. Introduction

The programs we have discussed thus far are generally structured as methods that call one another in a disciplined, hierarchical manner. For some problems, however, it is useful to have a method call itself. Such a method is known as a [recursive method](#). A recursive method can be called either directly, or indirectly through another method. Recursion is an important topic discussed at length in upper-level computer science courses. In this chapter, we consider recursion conceptually, then present several programs containing recursive methods. [Figure 15.1](#) summarizes the recursion examples and exercises in the book.

Figure 15.1. Summary of the 32 recursion examples and exercises in this text.

(This item is displayed on page 746 in the print version)

| Chapter | Recursion examples and exercises in this book                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## 15.2. Recursion Concepts

Recursive problem-solving approaches have a number of elements in common. When a recursive method is called to solve a problem, the method actually is capable of solving only the simplest case(s), or **base case(s)**. If the method is called with a base case, the method returns a result. If the method is called with a more complex problem, the method typically divides the problem into two conceptual pieces: a piece that the method knows how to do and a piece that the method does not know how to do. To make recursion feasible, the latter piece must resemble the original problem, but be a slightly simpler or smaller version of it. Because this new problem looks like the original problem, so the method calls a fresh copy of itself to work on the smaller problem; this is referred to as a **recursive call** and is also called the **recursion step**. The recursion step normally includes a **return** statement, because its result will be combined with the portion of the problem the method knew how to solve to form a result that will be passed back to the original caller. This concept of separating the problem into two smaller portions is a form of the divide-and-conquer approach introduced at the beginning of [Chapter 6](#).

The recursion step executes while the original call to the method is still active (i.e., while it has not finished executing). The recursion step can result in many more recursive calls as the method divides each new subproblem into two conceptual pieces. For the recursion to eventually terminate, each time the method calls itself with a simpler version of the original problem, the sequence of smaller and smaller problems must converge on a base case. At that point, the method recognizes the base case and returns a result to the previous copy of the method. A sequence of returns ensues until the original method call returns the final result to the caller.

---

[Page 746]

A recursive method may call another method, which may in turn make a call back to the recursive method. Such a process is known as an **indirect recursive call** or **indirect recursion**. For example, method **A** calls method **B**, which makes a call back to method **A**. This is still considered recursion, because the second call to method **A** is made while the first call to method **A** is active; that is, the first call to method **A** has not yet finished executing (because it is waiting on method **B** to return a result to it) and has not returned to method **A**'s original caller.

---

[Page 747]

To better understand the concept of recursion, let us look at an example of recursion that is quite common to computer users: the recursive definition of a directory on a computer. A computer normally stores related files in a directory. A directory can be empty, can contain files and/or can contain other directories (usually referred to as subdirectories). Each of these subdirectories, in turn, may also contain both files and directories. If we wanted to list each file in a directory (including all the files in the directory's subdirectories), we would need to create a method that first lists the initial directory's files, then makes recursive calls to list the files in each of that directory's subdirectories. The base case would occur when a directory is reached that does not contain any subdirectories. At this point, all the files in the original directory have been listed and no further recursive calls need to be made.

## 15.3. Example Using Recursion: Factorials

Let us write a recursive program to perform a popular mathematical calculation. Consider the factorial of a positive integer  $n$ , written  $n!$  (and pronounced " $n$ factorial"), which is the product

$$n \cdot (n-1) \cdot (n-2) \cdot \dots \cdot 1$$

with  $1!$  equal to 1 and  $0!$  defined to be 1. For example,  $5!$  is the product  $5 \cdot 4 \cdot 3 \cdot 2 \cdot 1$ , which is equal to 120.

The factorial of integer `number` (where `number`  $\geq 0$ ) can be calculated **iteratively** (non-recursively) using a `for` statement as follows:

```
factorial = 1;
for (int counter = number; counter >= 1; counter--)
 factorial *= counter;
```

A recursive declaration of the factorial method is arrived at by observing the following relationship:

$$n! = n \cdot (n-1)!$$

For example,  $5!$  is clearly equal to  $5 \cdot 4!$ , as is shown by the following equations:

$$\begin{aligned} 5! &= 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 \\ 5! &= 5 \cdot (4 \cdot 3 \cdot 2 \cdot 1) \\ 5! &= 5 \cdot (4!) \end{aligned}$$

The evaluation of  $5!$  would proceed as shown in [Fig. 15.2](#). [Figure 15.2\(a\)](#) shows how the succession of recursive calls proceeds until  $1!$  (the base case) is evaluated to be 1, which terminates the recursion. [Figure 15.2\(b\)](#) shows the values returned from each recursive call to its caller until the final value is calculated and returned.

Figure 15.2. Recursive evaluation of  $5!$ .

(This item is displayed on page 748 in the print version)

[\[View full size image\]](#)

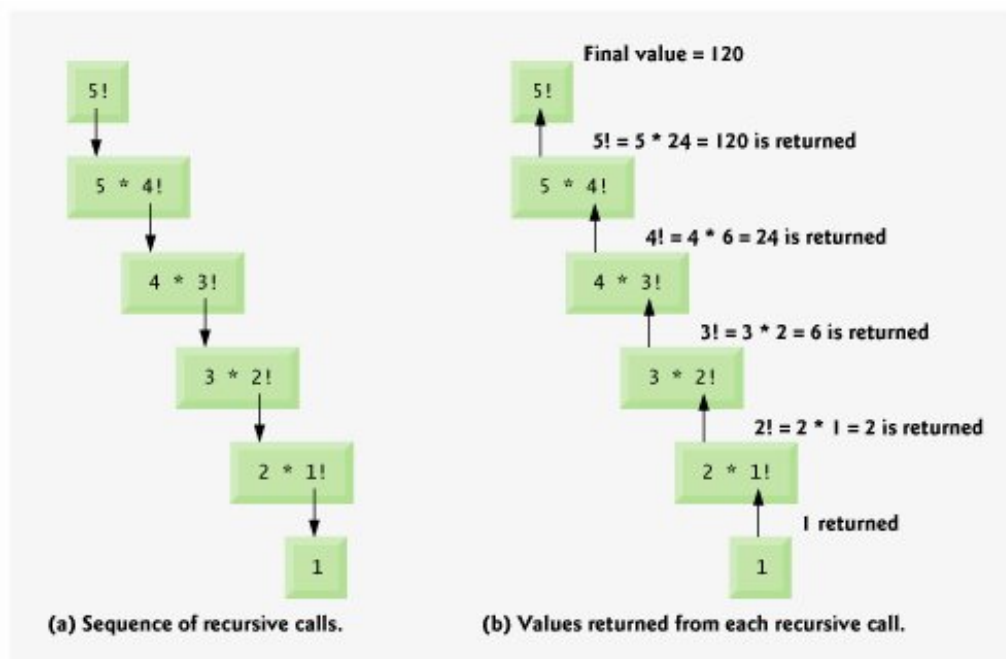

Figure 15.3 uses recursion to calculate and print the factorials of the integers from 0 to 10. The recursive method `factorial` (lines 7-13) first tests to determine whether a terminating condition (line 9) is `True`. If `number` is less than or equal to 1 (the base case), `factorial` returns 1, no further recursion is necessary and the method returns. If `number` is greater than 1, line 12 expresses the problem as the product of `number` and a recursive call to `factorial` evaluating the factorial of `number - 1`, which is a slightly simpler problem than the original calculation, `factorial( number )`.

Figure 15.3. Factorial calculations with a recursive method.

```

1 // Fig. 15.3: FactorialCalculator.java
2 // Recursive factorial method.
3
4 public class FactorialCalculator
5 {
6 // recursive method factorial
7 public long factorial(long number)
8 {
9 if (number <= 1) // test for base case
10 return 1; // base cases: 0! = 1 and 1! = 1
11 else // recursion step
12 return number * factorial(number - 1);
13 } // end method factorial
14
15 // output factorials for values 0-10
16 public void displayFactorials()
17 {
18 // calculate the factorials of 0 through 10
19 for (int counter = 0; counter <= 10; counter++)
20 System.out.printf("%d! = %d\n", counter, factorial(counter));
21 } // end method displayFactorials
22 } // end class FactorialCalculator

```

## Common Programming Error 15.1

*Either omitting the base case or writing the recursion step incorrectly so that it does not converge on the base case can cause a logic error known as **infinite recursion**, where recursive calls are continuously made until memory has been exhausted. This error is analogous to the problem of an infinite loop in an iterative (nonrecursive) solution.*

Method `displayFactorials` (lines 1621) displays the factorials of 0-10. The call to method `factorial` occurs in line 20. Method `factorial` receives a parameter of type `long` and returns a result of type `long`. [Figure 15.4](#) tests our `factorial` and `displayFactorials` methods by calling `displayFactorials` (line 10). As can be seen from the output of [Fig. 15.4](#), factorial values become large quickly. We use type `long` (which can represent relatively large integers) so the program can calculate factorials greater than 12!. Unfortunately, the `factorial` method produces large values so quickly that factorial values soon exceed the maximum value that can be stored even in a `long` variable.

Figure 15.4. Testing the `factorial` method.

```

1 // Fig. 15.4: FactorialTest.java
2 // Testing the recursive factorial method.
3
4 public class FactorialTest
5 {
6 // calculate factorials of 0-10
7 public static void main(String args[])
8 {
9 FactorialCalculator factorialCalculator = new FactorialCalculator();
10 factorialCalculator.displayFactorials();
11 } // end main
12 } // end class FactorialTest

```

```

0! = 1
1! = 1
2! = 2
3! = 6
4! = 24
5! = 120
6! = 720
7! = 5040
8! = 40320
9! = 362880
10! = 3628800

```

---

Due to the limitations of integral types, `float` or `double` variables may ultimately be needed to calculate factorials of larger numbers. This points to a weakness in most programming languagesnamely, that the languages are not easily extended to handle the unique application requirements. As we saw in [Chapter 9](#), Java is an extensible language that allows us to create arbitrarily large integers if we wish. In fact, package `java.math` provides classes `BigInteger` and `BigDecimal` explicitly for arbitrary precision mathematical calculations that cannot be performed with primitive types. For more information on these classes visit, [java.sun.com/j2se/5.0/docs/api/java/math/BigInteger.html](http://java.sun.com/j2se/5.0/docs/api/java/math/BigInteger.html) and [java.sun.com/j2se/5.0/docs/api/java/math/BigDecimal.html](http://java.sun.com/j2se/5.0/docs/api/java/math/BigDecimal.html), respectively.

## 15.4. Example Using Recursion: Fibonacci Series

The [Fibonacci series](#),

0, 1, 1, 2, 3, 5, 8, 13, 21, ...

begins with 0 and 1 and has the property that each subsequent Fibonacci number is the sum of the previous two Fibonacci numbers. This series occurs in nature and, in particular, describes a form of spiral. The ratio of successive Fibonacci numbers converges on a constant value of 1.618..., a number that has been called the [golden ratio](#) or the [golden mean](#). Humans tend to find the golden mean aesthetically pleasing. Architects often design windows, rooms and buildings whose length and width are in the ratio of the golden mean. Postcards are often designed with a golden-mean length-to-width ratio.

The Fibonacci series may be defined recursively as follows:

```
fibonacci(0) = 0
fibonacci(1) = 1
fibonacci(n) = fibonacci(n - 1) + fibonacci(n - 2)
```

Note that there are two base cases for the Fibonacci calculation: `fibonacci(0)` is defined to be 0, and `fibonacci(1)` is defined to be 1. The program in [Fig. 15.5](#) calculates the  $n^{\text{th}}$  Fibonacci number recursively, using method `fibonacci` (lines 713). Method `displayFibonacci` (lines 1520) tests `fibonacci`, displaying the Fibonacci values of 010. The variable `counter` created in the `for` header in line 17 indicates which Fibonacci number to calculate for each iteration of the `for` statement. The value of `counter` is stored in variable `number` (line 7) for each call to method `fibonacci`. Fibonacci numbers tend to become large quickly. Therefore, we use type `long` as the parameter type and the return type of method `fibonacci`. [Figure 15.6](#) calls method `displayFibonacci` (line 9) to calculate the Fibonacci values.

Figure 15.5. Fibonacci numbers generated with a recursive method.

```

1 // Fig. 15.5: FibonacciCalculator.java
2 // Recursive fibonacci method.
3
4 public class FibonacciCalculator
5 {
6 // recursive declaration of method fibonacci
7 public long fibonacci(long number)
8 {
9 if ((number == 0) || (number == 1)) // base cases
10 return number;
11 else // recursion step
12 return fibonacci(number - 1) + fibonacci(number - 2);
13 } // end method fibonacci
14
15 public void displayFibonacci()
16 {
17 for (int counter = 0; counter <= 10; counter++)
18 System.out.printf("Fibonacci of %d is: %d\n", counter,
19 fibonacci(counter));
20 } // end method displayFibonacci
21 } // end class FibonacciCalculator

```

Figure 15.6. Testing the **fibonacci** method.

(This item is displayed on page 751 in the print version)

```

1 // Fig. 15.6: FibonacciTest.java
2 // Testing the recursive fibonacci method.
3
4 public class FibonacciTest
5 {
6 public static void main(String args[])
7 {
8 FibonacciCalculator fibonacciCalculator = new FibonacciCalculator();
9 fibonacciCalculator.displayFibonacci();
10 } // end main
11 } // end class FibonacciTest

```

```
Fibonacci of 0 is: 0
Fibonacci of 1 is: 1
Fibonacci of 2 is: 1
Fibonacci of 3 is: 2
Fibonacci of 4 is: 3
Fibonacci of 5 is: 5
Fibonacci of 6 is: 8
Fibonacci of 7 is: 13
Fibonacci of 8 is: 21
Fibonacci of 9 is: 34
Fibonacci of 10 is: 55
```

[Page 751]

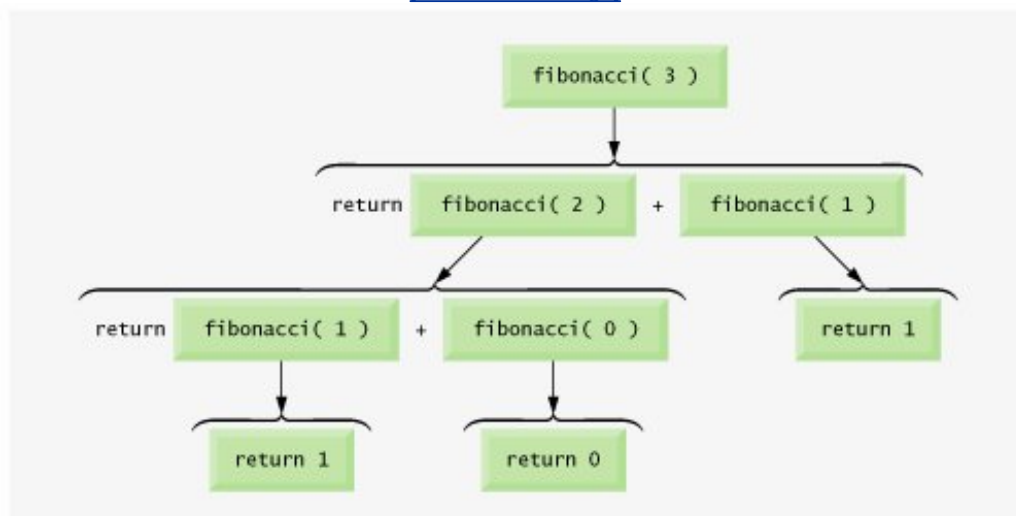

The call to method `fibonacci` (line 19 of [Fig. 15.5](#)) from `displayFibonacci` is not a recursive call, but all subsequent calls to `fibonacci` performed from the body of `fibonacci` (line 12 of [Fig. 15.5](#)) are recursive, because at that point the calls are initiated by method `fibonacci` itself. Each time `fibonacci` is called, it immediately tests for the base cases `number` equal to 0 or `number` equal to 1 (line 9). If this condition is true, `fibonacci` simply returns `number` because `fibonacci( 0 )` is 0, and `fibonacci( 1 )` is 1. Interestingly, if `number` is greater than 1, the recursion step generates *two* recursive calls (line 12), each for a slightly simpler problem than the original call to `fibonacci`.

[Figure 15.7](#) shows how method `fibonacci` evaluates `fibonacci( 3 )`. Note that at the bottom of the figure, we are left with the values 1, 0 and 1 the results of evaluating the base cases. The first two return values (from left to right), 1 and 0, are returned as the values for the calls `fibonacci( 1 )` and `fibonacci( 0 )`. The sum 1 plus 0 is returned as the value of `fibonacci( 2 )`. This is added to the result (1) of the call to `fibonacci( 1 )`, producing the value 2. This final value is then returned as the value of `fibonacci( 3 )`.

Figure 15.7. Set of recursive calls for `fibonacci( 3 )`.

(This item is displayed on page 752 in the print version)

[\[View full size image\]](#)

[Figure 15.7](#) raises some interesting issues about the order in which Java compilers evaluate the operands of

operators. This order is different from the order in which operators are applied to their operandsnamely, the order dictated by the rules of operator precedence. From [Figure 15.7](#), it appears that while `fibonacci( 3 )` is being evaluated, two recursive calls will be made`fibonacci( 2 )` and `fibonacci( 1 )`. But in what order will these calls be made? The Java language specifies that the order of evaluation of the operands is from left to right. Thus, the call `fibonacci( 2 )` is made first and the call `fibonacci( 1 )` is made second.

---

[Page 752]

A word of caution is in order about recursive programs like the one we use here to generate Fibonacci numbers. Each invocation of the `fibonacci` method that does not match one of the base cases (0 or 1) results in two more recursive calls to the `fibonacci` method. Hence, this set of recursive calls rapidly gets out of hand. Calculating the Fibonacci value of 20 with the program in [Fig. 15.5](#) requires 21,891 calls to the `fibonacci` method; calculating the Fibonacci value of 30 requires 2,692,537 calls! As you try to calculate larger Fibonacci values, you will notice that each consecutive Fibonacci number you use the application to calculate results in a substantial increase in calculation time and in the number of calls to the `fibonacci` method. For example, the Fibonacci value of 31 requires 4,356,617 calls, and the Fibonacci value of 32 requires 7,049,155 calls! As you can see, the number of calls to `fibonacci` increases quickly1,664,080 additional calls between Fibonacci values of 30 and 31 and 2,692,538 additional calls between Fibonacci values of 31 and 32! The difference in the number of calls made between Fibonacci values of 31 and 32 is more than 1.5 times the number of calls for Fibonacci values between 30 and 31. Problems of this nature can humble even the world's most powerful computers. [*Note:* In the field of complexity theory, computer scientists study how hard algorithms work to complete their tasks. Complexity issues are discussed in detail in the upper-level computer science curriculum course generally called "Algorithms." We introduce various complexity issues in [Chapter 16](#), Searching and Sorting.] In the exercises, you will be asked to enhance the Fibonacci program of [Fig. 15.5](#) such that it calculates the approximate amount of time required to perform the calculation. For this purpose, you will call `static System` method `currentTimeMillis`, which takes no arguments and returns the computer's current time in milliseconds.

## Performance Tip 15.1

*Avoid Fibonacci-style recursive programs, because they result in an exponential "explosion" of method calls.*

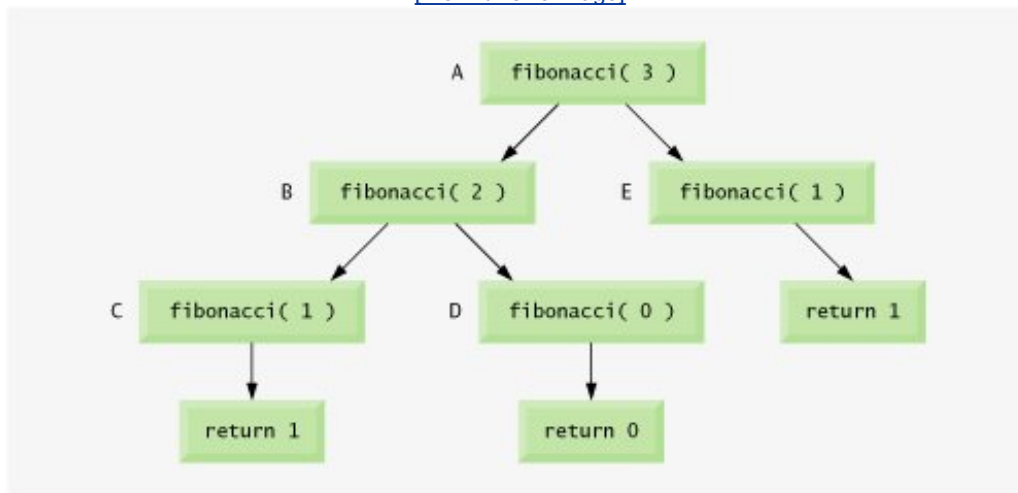

## 15.5. Recursion and the Method Call Stack

In [Chapter 6](#), the stack data structure was introduced in the context of understanding how Java performs method calls. We discussed both the method call stack (also known as the program execution stack) and activation records. In this section, we will use these concepts to demonstrate how the program execution stack handles recursive method calls.

Let us begin by returning to the Fibonacci examplespecifically, calling method `fibonacci` with the value `3`, as in [Fig. 15.7](#). To more easily demonstrate in what order the activation records for the method calls are placed on the stack, we have lettered the method calls, as shown in [Fig. 15.8](#).

Figure 15.8. Method calls made within the call `fibonacci ( 3 )`.

[\[View full size image\]](#)

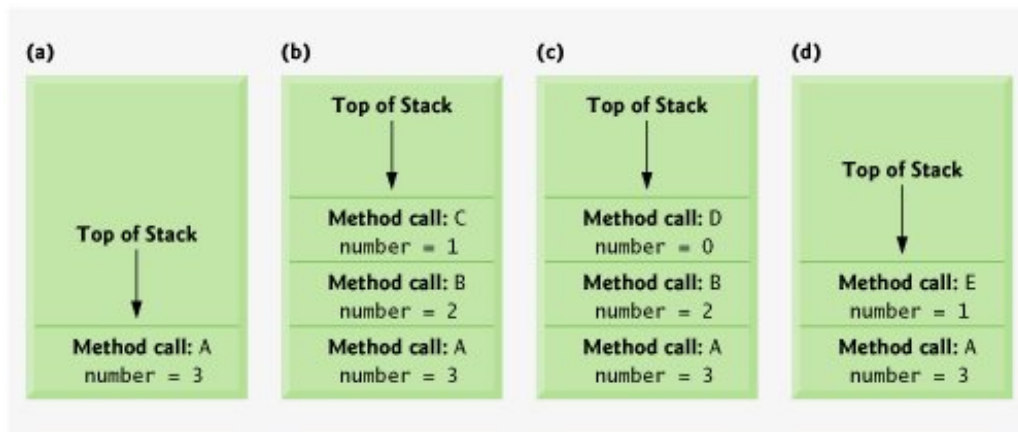

When the first method call (**A**) is made, an activation record is pushed onto the program execution stack which contains the value of the local variable `number` (`3`, in this case). The program execution stack, including the activation record for method call **A**, is illustrated in part a of [Fig. 15.9](#). [Note: In an actual computer, the program execution stack and its activation records would be more complex than in [Fig. 15.9](#), containing such information as where the method call is to return to when it has completed execution. We use a simplified stack to demonstrate how the program execution stack works.]

Figure 15.9. Method calls on the program execution stack.

(This item is displayed on page 754 in the print version)

[\[View full size image\]](#)

Within method call **A**, method calls **B** and **E** are made. The original method call has not yet completed, so its activation record remains on the stack. The first method call to be made from within **A** is method call **B**, so the activation record for method call **B** is pushed onto the stack on top of the activation record for method call **A**. Method call **B** must execute and complete before method call **E** is made. Within method call **B**, method calls **C** and **D** will be made. Method call **C** is made first, and its activation record is pushed onto the stack (part b of [Fig. 15.9](#)). Method call **B** has not yet finished, and its activation record is still on the method call stack. When method call **C** executes, it does not make any further method calls, but simply returns the value **1**. When this method returns, its activation record is popped off the top of the stack. The method call at the top of the stack is now **B**, which continues to execute by performing method call **D**. The activation record for method call **D** is pushed onto the stack (part c of [Fig. 15.9](#)). Method call **D** completes without making any more method calls, and returns the value **0**. The activation record for this method call is then popped off the stack. Now, both method calls made from within method call **B** have returned. Method call **B** continues to execute, returning the value **1**. Method call **B** completes and its activation record is popped off the stack. At this point, the activation record for method call **A** is at the top of the stack and the method continues its execution. This method makes method call **E**, whose activation record is now pushed onto the stack (part d of [Fig. 15.9](#)). Method call **E** completes and returns the value **1**. The activation record for this method call is popped off the stack, and once again method call **A** continues to execute. At this point, method call **A** will not be making any other method calls, and can finish its execution, returning the value **2** to **A**'s caller (**Fib(3) = 2**). **A**'s activation record is popped off the stack. Note that the current method executing is always the method whose activation record is at the top of the stack, and that the activation record for that method contains the values of the method's local variables.

## 15.6. Recursion vs. Iteration

In the preceding sections, we studied methods `factorial` and `fibonacci`, which can easily be implemented either recursively or iteratively. In this section, we compare the two approaches and discuss why the programmer might choose one approach over the other in a particular situation.

Both iteration and recursion are based on a control statement: Iteration uses a repetition statement (e.g., `for`, `while` or `do...while`), whereas recursion uses a selection statement (e.g., `if`, `if...else` or `switch`). Both iteration and recursion involve repetition: Iteration explicitly uses a repetition statement, whereas recursion achieves repetition through repeated method calls. Iteration and recursion each involve a termination test: Iteration terminates when the loop-continuation condition fails, whereas recursion terminates when a base case is reached. Iteration with counter-controlled repetition and recursion each gradually approach termination: Iteration keeps modifying a counter until the counter assumes a value that makes the loop-continuation condition fail, whereas recursion keeps producing simpler versions of the original problem until the base case is reached. Both iteration and recursion can occur infinitely: An infinite loop occurs with iteration if the loop-continuation test never becomes false, whereas infinite recursion occurs if the recursion step does not reduce the problem each time in a manner that converges on the base case, or if the base case is not tested.

To illustrate the differences between iteration and recursion, let us examine an iterative solution to the factorial problem ([Fig. 15.10](#)[Fig. 15.11](#)). Note that a repetition statement is used (lines 12-13 of [Fig. 15.10](#)) rather than the selection statement of the recursive solution (lines 9-12 of [Fig. 15.3](#)). Note that both solutions use a termination test. In the recursive solution, line 9 tests for the base case. In the iterative solution, line 12 tests the loop-continuation condition; if the test fails, the loop terminates. Finally, note that instead of producing simpler versions of the original problem, the iterative solution uses a counter that is modified until the loop-continuation condition becomes false.

3! = 6
4! = 24
5! = 120
6! = 720
7! = 5040
8! = 40320
9! = 362880
10! = 3628800

```

Recursion has many negatives. It repeatedly invokes the mechanism, and consequently the overhead, of method calls. This repetition can be expensive in terms of both processor time and memory space. Each recursive call causes another copy of the method (actually, only the method's variables, stored in the activation record) to be created. This set of copies can consume considerable memory space. Since iteration occurs within a method, repeated method calls and extra memory assignment are avoided. So why choose recursion?

*Any problem that can be solved recursively can also be solved iteratively (nonrecursively). A recursive approach is normally preferred over an iterative approach when the recursive approach more naturally mirrors the problem and results in a program that is easier to understand and debug. A recursive approach can often be implemented with fewer lines of code. Another reason to choose a recursive approach is that an iterative one might not be apparent.*

---

[Page 756]

## Performance Tip 15.2

*Avoid using recursion in situations requiring high performance. Recursive calls take time and consume additional memory.*

## Common Programming Error 15.2

*Accidentally having a nonrecursive method call itself either directly or indirectly through another method can cause infinite recursion.*

## 15.7. String Permutations

The example in this section provides a more in-depth walkthrough of how to solve a recursive problem, especially one that does not involve a simple mathematical formula. The problem we analyze in this section is creating the [permutations](#) of a string of text all the different strings that can be created by rearranging the characters of the original string. Words created from these strings are known as [anagrams](#). The permutations for the string "abc" are:

```
abc
acb
bac
bca
cab
cba
```

---

[Page 757]

Such a program could come in handy if one wants to unscramble a string of characters, determine all the words that can be created from a string, or determine all the words that can be created from the characters associated with a telephone number.

We have already provided a few recursive solutions in this chapter, but we have not considered the flow of thought that results in a recursive solution. We do this now, in the context of string permutations. To begin, we look for a pattern that can be used to solve the problem. In the preceding list of permutations, note that two of the resulting permutations start with "a" ("abc" and "acb"), two with "b" ("bac" and "bca"), and two with "c" ("cab", "cba"). For each letter, permutations are provided that begin with that letter, followed by permutations of the remaining letters. If we were to begin with the letter "b", for example, we would have two permutations "bac" and "bca". These are determined by simply looking at the remaining two letters, "a" and "c", and seeing that there are only two permutations using these letters namely, "ac" and "ca". Note that we have now just determined all the permutations on the smaller string, "ac". To do this, we can use the same thought process as before, namely, determining all the permutations that start with the letter "a" followed by all the permutations that start with the letter "c". If we start with the letter "a", we have only one letter left, the letter "c". For a string with only one character, the string itself is the only permutation.

We now have the permutations of our substrings, but not the final permutations as shown above. To create these, we need to precede the permutations of the substrings with the characters that were removed to create the substring. For example, when determining the permutations of "bac", we divided the string into two strings ("b" and "ac"), and determined the permutations of the second string (in this case, "ac" and "ca"). We need our solution to precede "ac" and "ca" with the character that was removed to create this substring (namely, "b"). Our solution will need a way to keep track of these removed letters.

We have now found a way to break up our problem into two pieces: a single character from the original string, concatenated with all the permutations of the remaining characters the recursion step calculates all such permutations. The recursion step includes a recursive call for each letter in the string, with a different letter being used as the first letter of the permutation. Each call takes a different character from the string being permuted, and creates a substring of the remaining values, to be passed to the recursive call. For instance, if we are using the example of "abc", the first call to our recursive method results in three recursive calls one which determines all the permutations that begin with "a" (where the substring is "bc"), one which determines all the permutations that begin with "b" (where the substring is "ac") and one which determines all the permutations that begin with "c" (where the substring is "ab").

We have now discovered the recursion step for our program (determining the permutations of the various

substrings) and our base case (a string with one letter will always have only one permutation, the letter itself). The next step is to ensure that the base case will be reached. Because our recursion step always calls with a string that is one character shorter than the string before it, we can be sure that we will always reach a string of one character the base case. Note that the base case also handles the situation where the user enters an empty string (i.e., one whose length is 0).

Now that we have determined our base case, the recursion step and that the base case will always be reached, we present the code for our solution ([Fig. 15.12](#)). Method `permuteString` (lines 738) takes two arguments. The first, `beginningString`, contains the characters that were removed from the string in previous calls and now need to precede the permutations that are being created. The second argument, `endingString`, contains the string that needs to be permuted (we call it `endingString` because for our final results it will be displayed after `beginningString`). When the method is called with the original string, the first argument will be the empty string, as there are no characters from previous calls that need to be added to the solution. The base case occurs in lines 1213, when the string being permuted contains only one character. In this case, we simply print the characters from previous calls (`beginningString`) followed by the character in `endingString`.

Figure 15.12. String permutations generated with a recursive method.

```
1 // Fig. 15.12: Permutation.java
2 // Recursive method to find all permutations of a String.
3
4 public class Permutation
5 {
6 // recursive declaration of method permuteString
7 private void permuteString(
8 String beginningString, String endingString)
9 {
10 // base case: if string to permute is length less than or equal to
11 // 1, just display this string concatenated with beginningString
12 if (endingString.length() <= 1)
13 System.out.println(beginningString + endingString);
14 else // recursion step: permute endingString
15 {
16 // for each character in endingString
17 for (int i = 0; i < endingString.length(); i++)
18 {
19 try
20 {
21 // create new string to permute by eliminating the
22 // character at index i
23 String newString = endingString.substring(0, i) +
24 endingString.substring(i + 1);
25
26 // recursive call with a new string to permute
27 // and a beginning string to concatenate, which
28 // includes the character at index i
29 permuteString(beginningString +
30 endingString.charAt(i), newString);
31 } // end try
32 catch (StringIndexOutOfBoundsException exception)
33 {
34 exception.printStackTrace();
35 } // end catch
36 } // end for
37 } // end else
38 }
39 }
```

```
38 } // end method permuteString
39 } // end class Permutation
```

The recursion step occurs in lines 1437. The `for` statement makes a recursive call for each of the substrings. The current character being removed is the character returned from `endingString.charAt( i )`. Method `charAt` takes an integer argument and returns the character in the `String` at that index. As with arrays, the first element of a string is considered to be at position 0. The `for` statement iterates through each character in `endingString`, so that permutations will be created that begin with each letter in `endingString`.

---

[Page 759]

To create the substring that needs to be permuted, the character at index `i` needs to be removed from the string that will be passed in the recursive call. To remove a character, we concatenate two substrings: the first substring contains all the characters that occur before the character being removed, and the second substring contains the portion of the string that occurs after the character being removed. For instance, to remove the character "s" from the word "recursion," we create the new string by concatenating the first substring, "recur", with "ion", resulting in "recurion." Lines 2324 create this substring using `String` method `substring`. Class `String` provides two `substring` methods to return a new `String` object created by copying part of an existing `String` object. The call in line 23 passes method `substring` two integers (`0` and `i`). The first argument specifies the starting index in the original string from which characters are copied. The second argument specifies the index one beyond the last character to be copied (i.e., copy up to, but not including, that index in the string). The substring returned contains copies of the specified range of characters from the original string. Therefore, the method call in line 23 returns all the characters from the beginning of `endingString` up to, but not including, the character at index `i` (the character we are trying to remove). If the arguments are outside the bounds of the string, the program generates a `StringIndexOutOfBoundsException` (handled in lines 3235).

The method call in line 24 uses the `substring` method that takes one integer argument (`i + 1`), which specifies the starting index in the original string from which characters are to be copied. The substring returned contains a copy of the characters from the starting index to the end of the string. Therefore, the method call in line 24 returns all the characters that occur after the character we are trying to remove. If the argument is outside the bounds of the string, the program generates a `StringIndexOutOfBoundsException` (also handled in lines 3235).

Lines 2930 perform the recursive call. The first argument passed is `beginningString` concatenated with `endingString.charAt( i )`. This way we combine the characters isolated from previous calls (`beginningString`) with the character being isolated in this call. The second argument is `newString`, which is the substring to be permuted.

[Figure 15.13](#) tests our recursive method. Line 9 creates a `Scanner` object to read a string in from the keyboard. Line 10 creates a `Permutation` object with which to call method `permuteString`. The string is read in at line 13 and passed to method `permuteString` in line 16. Note that this call provides an empty string as the first argument and the string to permute as the second argument. Because we have not yet removed any characters from the string, `beginningString` (the first argument) should be an empty string. Some programmers may want to define method `permuteString` as `private`, and create another `public` method that takes only the string to permute. This method could then call `permuteString` with the empty string as the first argument and the string to permute as the second argument. This would ensure that the user does not enter something other than the empty string as the first argument to method `permuteString`.

The permutations will be printed to the command prompt. Note that if a string is entered with repeated characters (e.g., "hello"), each character is treated on its own, resulting in repeated permutations. One way to handle this problem is to store permutations as they are created when each new permutation is formed, check the previously created strings and add the new string only if it has not already appeared. Finally, note from the output that there are 24 permutations for the string "math". The number of unique permutations for a string with  $n$  unique characters is equal to the factorial of  $n$  (i.e., there are four characters in "math", resulting in  $4!$  permutations, or 24 permutations).

## 15.8. Towers of Hanoi

In the preceding sections of this chapter, we studied methods that can be easily implemented both recursively and iteratively. In this section, we present a problem whose recursive solution demonstrates the elegance of recursion, and whose iterative solution may not be as apparent.

The [Towers of Hanoi](#) is one of the most famous classic problems every budding computer scientist must grapple with. Legend has it that in a temple in the Far East, priests are attempting to move a stack of golden disks from one diamond peg to another ([Fig. 15.14](#)). The initial stack has 64 disks threaded onto one peg and arranged from bottom to top by decreasing size. The priests are attempting to move the stack from one peg to another under the constraints that exactly one disk is moved at a time and at no time may a larger disk be placed above a smaller disk. Three pegs are provided, one being used for temporarily holding disks. Supposedly, the world will end when the priests complete their task, so there is little incentive for us to facilitate their efforts.

Figure 15.14. Towers of Hanoi for the case with four disks.

Let us assume that the priests are attempting to move the disks from peg 1 to peg 3. We wish to develop an algorithm that prints the precise sequence of peg-to-peg disk transfers.

If we were to approach this problem with conventional methods, we would rapidly find ourselves hopelessly knotted up in managing the disks. Instead, attacking this problem with recursion in mind allows the steps to be simple. Moving  $n$  disks can be viewed in terms of moving only  $n - 1$  disks (hence the recursion) as follows:

- Move  $n - 1$  disks from peg 1 to peg 2, using peg 3 as a temporary holding area.
- Move the last disk (the largest) from peg 1 to peg 3.
- Move the  $n - 1$  disks from peg 2 to peg 3, using peg 1 as a temporary holding area.

The process ends when the last task involves moving  $n = 1$  disk (i.e., the base case). This task is

accomplished by simply moving the disk, without the need for a temporary holding area.

[Figure 15.15](#) displays the precise instructions it will take to move the disks from the starting peg to the destination peg. In the constructor (lines 912), the number of disks to be moved (`numDisks`) is initialized. Method `solveTowers` (lines 1534) solves the Towers of Hanoi puzzle given the total number of disks (in this case 3), the starting peg, the ending peg, and the temporary holding peg as parameters. The base case (lines 1923) occurs when only one disk needs to be moved from the starting peg to the ending peg. In the recursion step (lines 2733), line 27 moves `disks - 1` disks from the first peg (`sourcePeg`) to the temporary holding peg (`tempPeg`). When all but one of the disks have been moved to the temporary peg, line 30 records the step to move one disk, the largest one, from the start peg to the destination peg. Line 33 finishes the rest of the moves by calling the method `solveTowers` to recursively move `disks - 1` disks from the temporary peg (`tempPeg`) back to the destination peg (`destinationPeg`), this time using the first peg (`sourcePeg`) as the temporary peg.

Figure 15.15. Towers of Hanoi solution with a recursive method.

```
1 // Fig. 15.15: TowersOfHanoi.java
2 // Program solves the towers of Hanoi problem, and
3 // demonstrates recursion.
4
5 public class TowersOfHanoi
6 {
7 int numDisks; // number of disks to move
8
9 public TowersOfHanoi(int disks)
10 {
11 numDisks = disks;
12 } // end TowersOfHanoi constructor
13
14 // recursively move disks through towers
15 public void solveTowers(int disks, int sourcePeg, int destinationPeg,
16 int tempPeg)
17 {
18 // base case -- only one disk to move
19 if (disks == 1)
20 {
21 System.out.printf("\n%d --> %d", sourcePeg, destinationPeg);
22 return;
23 } // end if
24
25 // recursion step -- move disk to tempPeg, then to destinationPeg
26 // move (disks - 1) disks from sourcePeg to tempPeg recursively
27 solveTowers(disks - 1, sourcePeg, tempPeg, destinationPeg);
28
29 // move last disk from sourcePeg to destinationPeg
30 System.out.printf("\n%d --> %d", sourcePeg, destinationPeg);
31
32 // move (disks - 1) disks from tempPeg to destinationPeg
33 solveTowers(disks - 1, tempPeg, destinationPeg, sourcePeg);
34 } // end method solveTowers
35 } // end class TowersOfHanoi
```

[Figure 15.16](#) tests our Towers of Hanoi solution. In the `main` method (lines 616), line 12 creates a

`TowersOfHanoi` object, passing as a parameter the total number of disks to be moved from one peg to another. Line 15 calls the recursive `solveTowers` method which outputs the steps to the command prompt.

Figure 15.16. Testing the Towers of Hanoi solution.

```

## 15.9. Fractals

A [fractal](#) is a geometric figure that often can be generated from a pattern repeated recursively an infinite number of times ([Fig. 15.17](#)). The figure is modified by applying the pattern to each segment of the original figure. Real geometric figures do not have their patterns repeated an infinite number of times, but after several repetitions appear as they would if repeated infinitely. We will look at a few such approximations in this section. [*Note:* We will refer to our geometric figures as fractals, even though they are approximations.] Although these figures had been studied before the 20th century, it was the Polish mathematician Benoit Mandelbrot who introduced the term "fractal" in the 1970s, along with the specifics of how a fractal is created and the practical applications of fractals. Mandelbrot's fractal geometry provides mathematical models for many complex forms found in nature, such as mountains, clouds and coastlines. Fractals have many uses in mathematics and science. Fractals can be used to better understand systems or patterns that appear in nature (e.g., ecosystems), in the human body (e.g., in the folds of the brain), or in the universe (e.g., galaxy clusters). Drawing fractals has become a popular art form. Fractals have a [self-similar property](#) when subdivided into parts, each resembles a reduced-size copy of the whole. Many fractals yield an exact copy of the original when a portion of the original image is magnified such a fractal is said to be [strictly self similar](#). Links are provided in [Section 15.12](#) for various Web sites that discuss and demonstrate fractals.

Figure 15.17. Koch Curve fractal.

[\[View full size image\]](#)

As an example, let us look at a popular strictly self-similar fractal known as the [Koch Curve \(Fig. 15.17\)](#). This fractal is formed by removing the middle third of each line in the drawing and replacing it with two lines that form a point, such that if the middle third of the original line remained, an equilateral triangle would be formed. Formulas for creating fractals often involve removing all or part of the previous fractal image. This pattern has already been determined for this fractal in this section we focus not on how to determine what formulas are needed for a specific fractal, but how to use those formulas within a recursive solution. Most formulas can be used to create fractals, but not all fractals will resemble objects in nature.

We start with a straight line ([Fig. 15.17, Part a](#)) and apply the pattern, creating a triangle from the middle third ([Fig. 15.17, Part b](#)). We then apply the pattern again to each straight line, resulting in [Fig. 15.17, Part c](#). Each time the pattern is applied, we say that the fractal is at a new [level](#), or [depth](#) (sometimes the term [order](#) is also used). Fractals can be displayed at many levels for instance, a fractal at level 3 has had three iterations of the pattern applied ([Fig. 15.17, Part d](#)). After only a few iterations, this fractal begins to look the same, like a portion of a snowflake ([Fig. 15.17, Parts e and f](#)). The applications of the pattern are now too small for the human eye to see a difference. Since this is a strictly self-similar fractal, each portion of the fractal contains an exact copy of the fractal. In [Part f](#) of [Fig. 15.17](#), for example, we have highlighted a portion of the fractal with a dashed red box. If the image in this box were increased in size, it would look exactly like the entire fractal of [Part f](#).

There is a similar fractal, the [Koch Snowflake](#), which is the same as the Koch Curve but begins with a triangle rather than a line. The same pattern is applied to each side of the triangle, resulting in an image that looks like an enclosed snowflake. We have chosen to focus on the Koch Curve for simplicity. We will be moving on shortly to another fractal, but if the reader wishes to learn more about the Koch Curve and Koch Snowflake, see the links in [Section 15.12](#).

We now demonstrate the use of recursion to draw fractals by writing a program to create a strictly self-similar fractal. We call this the "Lo fractal," named for Sin Han Lo, a Deitel & Associates colleague who created it. The fractal will eventually resemble one-half of a feather (see the outputs in [Fig. 15.24](#)). The base case, or fractal level of 0, begins as a line between two points, **A** and **B** ([Fig. 15.18](#)). To create the next higher level, we find the midpoint (**C**) of the line. To calculate the location of point **C**, use the following formula: [*Note:* The **x** and **y** to the left of each letter refer to the *x*-coordinate and *y*-coordinate of that point, respectively. For instance, **xA** refers to the *x*-coordinate of point **A**, while **yC** refers to the *y*-coordinate of point **C**. In our diagrams we denote the point by its letter, followed by two numbers representing the *x*- and *y*-coordinates.]

$$xC = (xA + xB) / 2;$$

$$yC = (yA + yB) / 2;$$

Figure 15.18'. "Lo fractal" at level 0.

(This item is displayed on page 766 in the print version)

[\[View full size image\]](#)

To create this fractal, we also must find a point **D** that lies left of segment **AC** and creates an isosceles right triangle **ADC**. To calculate the location of point **D**, use the following formulas:

$$xD = xA + (xC - xA) / 2 - (yC - yA) / 2;$$

$$yD = yA + (yC - yA) / 2 + (xC - xA) / 2;$$

We continue the example in [Fig. 15.18](#) by moving on to the next level (from level 0 to level 1) as follows: First, add points **C** and **D** (as in [Fig. 15.19](#)). Then, remove the original line and add segments **DA**, **DC** and **DB**. The remaining lines curve at an angle, causing our fractal to look like a feather. For the next level of the fractal, this algorithm is repeated on each of the three lines in level 1. For each line, the formulas above are applied, where the former point **D** is now considered to be point **A**, while the other end of each line is considered to be point **B**. [Figure 15.20](#) contains the line from level 0 (now a dashed line) and the three added lines from level 1. We have changed point **D** to be point **A**, and the original points **A**, **C** and **B** to **B1**, **B2** and **B3** (the numbers are used to differentiate the various points). The preceding formulas have been used to find the new points **C** and **D** on each line. These points are also numbered 13 to keep track of which point is associated with each line. The points **C1** and **D1**, for instance, represent points **C** and **D** associated with the line formed from points **A** to **B1**. To achieve level 2, the three lines in [Fig. 15.20](#) are removed and replaced with new lines from the **C** and **D** points just added. [Figure 15.21](#) shows the new lines (the lines from level 2

are shown as dashed lines for your convenience). [Figure 15.22](#) shows level 2 without the dashed lines from level 1. Once this process has been repeated several times, the fractal created will begin to look like one-half of a feather, as shown in the output of [Fig. 15.24](#). We will discuss the code for this application shortly.

[\[View full size image\]](#)

[\[View full size image\]](#)

The application in [Fig. 15.23](#) defines the user interface for drawing this fractal (shown at the end of [Fig. 15.24](#)). The interface consists of three buttons one for the user to change the color of the fractal, one to

increase the level of recursion and one to decrease the level of recursion. A `JLabel` will keep track of the current level of recursion, which is modified by calling method `setLevel`, to be discussed shortly. Lines 1516 specify constants `WIDTH` and `HEIGHT` to be 400 and 480 respectively for the size of the `JFrame`. The default color to draw the fractal will be blue (line 18). The user triggers an `ActionEvent` by clicking the **Color** button. The event handler for this button is registered in lines 3854. The method `actionPerformed` displays a `JColorChooser`. This dialog returns the selected `Color` object or blue (if the user presses **Cancel** or closes the dialog without pressing **OK**). Line 51 calls the `setColor` method in class `FractalJPanel` to update the color.

---

[Page 767]

The event handler for the **Decrease Level** button is registered in lines 6078. In method `actionPerformed`, lines 6667 retrieve the current level of recursion and decrement it by 1. Line 70 checks to make sure that the level is greater than or equal to 0 (`MIN_LEVEL`). This is because the fractal is not defined for any recursion level lower than 0. The program allows the user to go up to any desired level, but it is important to note that at a certain point (level 10 and higher in this example) the rendering of the fractal becomes increasingly slower, as there is a lot of detail to be drawn. Lines 7274 reset the level label to reflect the change the new level is set and the `repaint` method is called to update the image to show the fractal corresponding to the new level.

---

[Page 770]

The **Increase Level** `JButton` works the same way as the **Decrease Level** `JButton`, except that the level is incremented rather than decremented to show more details of the fractal (lines 9091). When the application is first executed, the level will be set to 0, which will display a blue line between two points that were specified in the `FractalJPanel` class.

The `FractalJPanel` class in [Fig. 15.24](#) specifies the dimensions of the drawing `JPanel` to be 400 by 400 (lines 1314). The `FractalJPanel` constructor (lines 1824) takes the current level as a parameter and assigns it to its instance variable `level`. Instance variable `color` is set to the default color blue. Lines 2223 change the background color of the `JPanel` to be white (for visibility of the colors used to draw the fractal), and set the new dimensions of the `JPanel` where the fractal will be drawn.

---

[Page 771]

---

[Page 774]

Lines 2750 define the recursive method that creates the fractal. This method takes six parameters: the level, four integers that specify the  $x$  and  $y$  coordinates of two points, and the `Graphics` object `g`. The base case for this method (line 31) occurs when level equals 0, at which time a line will be drawn between the two points given as parameters. Lines 3643 calculate `(xC, yC)`, the midpoint between `(xA, yA)` and `(xB, yB)`, and `(xD, yD)`, the point that creates a right isosceles triangle with `(xA, yA)` and `(xC, yC)`. Lines 4648 make three recursive calls on three different sets of points.

In method `paintComponent`, line 59 makes the first call to method `drawFractal` to start the drawing. This method call is not recursive, but all subsequent calls to `drawFractal` performed from the body of `drawFractal` are. Since the lines will not be drawn until the base case is reached, the distance between two points decreases on each recursive call. As the level of recursion increases, the fractal becomes smoother and more detailed. The shape of this fractal stabilizes as the level approaches 11. Fractals will stabilize at different levels based on the shape and size of the fractal.

[Fig. 15.24](#) shows the development of the fractal from level zero to six. The last image shows the defining shape of the fractal at level 11. If we focus on one of the arms of this fractal, it would be identical to the whole image. This property defines the fractal to be strictly self-similar. See [Section 15.12](#) for further resources on fractals.

## 15.10. Recursive Backtracking

In this chapter's examples, our recursive methods all have a similar architecture: if the base case is reached, return a result; if not, make one or more recursive calls. In this section we will explore a recursive method that is slightly more complex. This method finds a path through a maze, returning true if there is a possible solution to the maze. The solution involves moving through the maze one step at a time where moves can be made by going down, right, up or left (diagonal moves are not permitted). From the current location in the maze (starting with the entry point), the following steps are taken: A direction is chosen, the move is made in that direction and a recursive call is made to solve the remainder of the maze from the new location. When a dead end is reached (i.e., we cannot take any more steps forward without hitting a wall), we back up to the previous location and try to go in a different direction. If there is no other direction that can be taken, we back up again. This process continues until we find a point in the maze where a move can be made in another direction. Once such a location is found, we move in the new direction and continue with another recursive call to solve the rest of the maze.

To back up to the previous location in the maze, our recursive method simply returns false, moving up the method-call chain to the previous recursive call (which references the previous location in the maze). This process of using recursion to return to an earlier decision point is known as [recursive backtracking](#). If one set of recursive calls does not result in a solution to the problem, the program backs up to the previous decision point and makes a different decision, often resulting in another set of recursive calls. In this example, the previous decision point is the previous location in the maze, and the decision to be made is the direction that the next move should take. One direction has led to a dead end, so the search continues with a different direction. Unlike our other recursive programs, which reached the base case and then returned all the way up the method-call chain to the original method call, the recursive backtracking solution to the maze problem uses recursion to return only part of the way up the method-call chain, then try a different direction. If the backtracking reaches the entry location of the maze and the paths in all directions have been attempted, the maze does not have a solution.

In the chapter exercises you are asked to implement recursive backtracking solutions to the maze problem ([Exercise 15.20](#), [Exercise 15.21](#) and [Exercise 15.22](#)) and the Eight Queens problem ([Exercise 15.15](#)), which attempts to find a way to place eight queens on an empty chessboard so that no queen is "attacking" any other (i.e., no two queens are in the same row, in the same column or along the same diagonal). See [Section 15.12](#) for links to further information on recursive backtracking.

## 15.11. Wrap-Up

In this chapter, you learned how to create recursive methods*i.e.*, methods that call themselves. You learned that recursive methods typically divide a problem into two conceptual piecesa piece that the method knows how to do (the base case) and a piece that the method does not know how to do (the recursion step). The recursion step is a slightly simpler version of the original problem, and is performed by a recursive method call. You saw some popular recursion examples, including calculating factorials and producing values in the Fibonacci series. You the learned how recursion works "under the hood," including the order in which recursive method calls are pushed on or popped off the program execution stack. Next, you learned the differences between recursive and iterative (non-recursive) methods. In that discussion, you learned that iterative solutions usually use a repetition statement, whereas recursive solutions usually use a selection statement. You learned how to solve more complex problems using recursion, including finding all permutations of a string and displaying fractals. The chapter concluded with an introduction to recursive backtracking, a technique for solving problems that involves backing up through recursive calls to try different possible solutions. In the next chapter, you will learn numerous techniques for sorting lists of data and searching for an item in a list of data, and under what circumstances each searching and sorting technique should be used.

## 15.12. Internet and Web Resources

### Recursion Concepts

[chortle.ccsu.ctstateu.edu/cs151/cs151java.html](http://chortle.ccsu.ctstateu.edu/cs151/cs151java.html)

Provides links to files that discuss recursion in detail, using questions to guide the reader.

[en.wikipedia.org/wiki/Recursion](http://en.wikipedia.org/wiki/Recursion)

Article from Wikipedia (an online encyclopedia) provides the basics of recursion and several resources for students.

[www.cafeaulait.org/javatutorial.html](http://www.cafeaulait.org/javatutorial.html)

Provides a nice, brief introduction to recursion in Java, and also covers other Java topics.

### Stacks

[www.cs.auc.dk/~normark/eciu-recursion/html/recit-slide-implerec.html](http://www.cs.auc.dk/~normark/eciu-recursion/html/recit-slide-implerec.html)

Provides slides discussing the implementation of recursion using stacks.

[faculty.juniata.edu/kruse/cs2java/recurimpl.htm](http://faculty.juniata.edu/kruse/cs2java/recurimpl.htm)

Provides a detailed diagram of the program execution stack and discusses how the stack works.

### Fractals

[math.rice.edu/~lanius/frac/](http://math.rice.edu/~lanius/frac/)

Provides examples of other fractals, such as the Koch Snowflake, the Sierpinski gasket, and Jurassic Park fractals.

[www.lifesmith.com/](http://www.lifesmith.com/)

Provides hundreds of colorful fractal images along with detailed explanation about the Mandelbrot and Julia sets, two common sets of fractals.

[www.jracademy.com/~jtucek/math/fractals.html](http://www.jracademy.com/~jtucek/math/fractals.html)

Contains two AVI movies created by zooming in continuously on the fractals known as the Mandelbrot and Julia equation sets.

[www.faqs.org/faqs/fractal-faq/](http://www.faqs.org/faqs/fractal-faq/)

Provides answers to many questions about fractals.

[spanky.triumf.ca/www/fractint/fractint.html](http://spanky.triumf.ca/www/fractint/fractint.html)

Contains links to download Fractint, a freeware program for generating fractals.

Lists URLs on fractals and software tools that create fractals.

[www.arcytech.org/java/fractals/koch.shtml](http://www.arcytech.org/java/fractals/koch.shtml)

Provides a detailed introduction to the Koch Curve fractal and provides an applet demonstrating the fractal.

[www.cs.ttu.edu/~denton/fractals/Koch.html](http://www.cs.ttu.edu/~denton/fractals/Koch.html)

Introduces the Koch fractals, providing source code in Java.

[library.thinkquest.org/26688/koch.html](http://library.thinkquest.org/26688/koch.html)

Displays a Koch Curve applet and provides the source code.

## Recursive Backtracking

[www.cs.sfu.ca/CourseCentral/201/havens/notes/Lecture14.pdf](http://www.cs.sfu.ca/CourseCentral/201/havens/notes/Lecture14.pdf)

Provides a brief introduction to recursive backtracking, including an example on planning a travel route.

[www.cs.utexas.edu/users/scottm/cs307/handouts/Slides/lec11RecursiveBacktracking-4Up.pdf](http://www.cs.utexas.edu/users/scottm/cs307/handouts/Slides/lec11RecursiveBacktracking-4Up.pdf)

Demonstrates recursive backtracking and walks through several examples.

[math.hws.edu/xJava/PentominosSolver](http://math.hws.edu/xJava/PentominosSolver)

Provides a program that uses recursive backtracking to solve a problem known as the Pentominos puzzle (described at the site).

[cte.rockhurst.edu/burgerk/research/scramble/paper.pdf](http://cte.rockhurst.edu/burgerk/research/scramble/paper.pdf)

Demonstrates using recursive backtracking to solve a scrambled squares puzzle.

## Summary

- A recursive method is a method that calls itself directly or indirectly through another method.
- When a recursive method is called to solve a problem, the method actually is capable of solving only the simplest case(s), or base case(s). If the method is called with a base case, the method returns a result.
- If a recursive method is called with a more complex problem than a base case, the method typically divides the problem into two conceptual pieces: a piece that the method knows how to do and a piece that the method does not know how to do.

---

[Page 777]

- To make recursion feasible, the piece that the method does not know how to do must resemble the original problem, but be a slightly simpler or smaller version of it. Because this new problem looks like the original problem, the method calls a fresh copy of itself to work on the smaller problem; this is called the recursion step.
- For recursion to eventually terminate, each time a method calls itself with a simpler version of the original problem, the sequence of smaller and smaller problems must converge on a base case. When the method recognizes the base case, it returns a result to the previous copy of the method.
- A recursive call may be a call to another method, which in turn makes a call back to the original method. Such a process still results in a recursive call to the original method. This is known as an indirect recursive call or indirect recursion.
- Either omitting the base case or writing the recursion step incorrectly so that it does not converge on the base case can cause infinite recursion, eventually exhausting memory. This error is analogous to the problem of an infinite loop in an iterative (nonrecursive) solution.
- The Fibonacci series begins with 0 and 1 and has the property that each subsequent Fibonacci number is the sum of the preceding two Fibonacci numbers.
- The ratio of successive Fibonacci numbers converges on a constant value of 1.618..., a number that has been called the golden ratio or the golden mean.
- Some recursive solutions, such as Fibonacci (which makes two calls per recursion step), result in an "explosion" of method calls.
- The stack is a data structure whose data objects can be added or removed only at the top of the stack.
- A stack is analogous to a pile of dishes. When a dish is placed on the pile, it is always placed at the top (referred to as pushing the dish onto the stack). Similarly, when a dish is removed from the pile, it is always removed from the top (referred to as popping the dish off the stack).
- Stacks are known as last-in, first-out (LIFO) data structures; the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.
- Stacks have many interesting applications. For example, when a program calls a method, the called method must know how to return to its caller, so the return address of the calling method is pushed onto the program execution stack (sometimes referred to as the method call stack).
- The program execution stack contains the memory for local variables on each invocation of a method during a program's execution. This data, stored as a portion of the program execution stack, is known

as the activation record or stack frame of the method call.

- If there are more recursive or nested method calls than can be stored on the program execution stack, an error known as a stack overflow occurs.
  - Both iteration and recursion are based on a control statement: Iteration uses a repetition statement, whereas recursion uses a selection statement.
  - Both iteration and recursion involve repetition: Iteration explicitly uses a repetition statement, whereas recursion achieves repetition through repeated method calls.
  - Iteration and recursion each involve a termination test: Iteration terminates when the loop-continuation condition fails, whereas recursion terminates when a base case is recognized.
  - Iteration with counter-controlled repetition and recursion each gradually approach termination: Iteration keeps modifying a counter until the counter assumes a value that makes the loop-continuation condition fail, whereas recursion keeps producing simpler versions of the original problem until the base case is reached.
  - Both iteration and recursion can occur infinitely: An infinite loop occurs with iteration if the loop-continuation test never becomes false, whereas infinite recursion occurs if the recursion step does not reduce the problem each time in a manner that converges on the base case.
- 

[Page 778]

- Recursion repeatedly invokes the mechanism, and consequently the overhead, of method calls.
- Any problem that can be solved recursively can also be solved iteratively.
- A recursive approach is normally preferred over an iterative approach when the recursive approach more naturally mirrors the problem and results in a program that is easier to understand and debug.
- A recursive approach can often be implemented with few lines of code, but a corresponding iterative approach might take a large amount of code. Another reason to choose a recursive solution is that an iterative solution might not be apparent.
- The permutations of a string are all the different strings that can be created by rearranging the characters of the original string.
- Method `charAt` of class `String` takes an integer argument and returns the character in the `String` at that index. As with arrays, the first element of a string is considered to be at position `0`.
- Class `String` provides two `substring` methods to enable a new `String` object to be created by copying part of an existing `String` object. Each method returns a new `String` object.
- If method `substring` is passed two integer arguments, the first argument specifies the starting index from which characters are copied in the original string, and the second argument specifies the index one beyond the last character to be copied.
- If method `substring` is passed one integer argument, the argument specifies the starting index in the original string from which characters are to be copied. The substring returned contains a copy of the characters from the starting index to the end of the string.
- A fractal is a geometric figure that is generated from a pattern repeated recursively an infinite number of times. The figure grows by adding the pattern at different orientations and scaling to the original.
- Fractals have a self-similar property when subdivided into parts, each is a reduced-size copy of the whole.
- The process of using recursion to return to an earlier decision point is known as recursive backtracking. If one set of recursive calls does not result in a solution to the problem, the program backs up to the previous decision point and makes a different decision, often resulting in another set of recursive calls.

## Self-Review Exercises

15.1 State whether each of the following is *true* or *false*. If *false*, explain why.

- a. A method that calls itself indirectly is not an example of recursion.
- b. Recursion can be efficient in computation because of reduced memory space usage.
- c. When a recursive method is called to solve a problem, the method actually is capable of solving only the simplest case(s), or base case(s).
- d. To make recursion feasible, the recursion step in a recursive solution must resemble the original problem, but be a slightly larger version of it.

15.2 A \_\_\_\_\_ is needed to terminate recursion.

- a. recursion step
- b. `break` statement
- c. `void` return type
- d. base case

15.3 The first call to invoke a recursive method is \_\_\_\_\_.

- a. not recursive
- b. recursive
- c. the recursion step
- d. none of the above

15.4 Each time a fractal's pattern is applied, the fractal is said to be at a new \_\_\_\_\_.

- a. width
- b. height
- c. level
- d. volume

15.5 Iteration and recursion each involve a \_\_\_\_\_.

- a. repetition statement

- b. termination test
- c. counter variable
- d. None of the above

15.6 Fill in the blanks in each of the following statements:

- a. The ratio of successive Fibonacci numbers converges on a constant value of 1.618..., a number that has been called the \_\_\_\_\_ or the \_\_\_\_\_.
  - b. Data can be added or removed only from the \_\_\_\_\_ of the stack.
  - c. Stacks are known as \_\_\_\_\_ data structures; the last item pushed (inserted) on the stack is the first item popped (removed) from the stack.
  - d. The program execution stack contains the memory for local variables on each invocation of a method during a program's execution. This data, stored as a portion of the program execution stack, is known as the \_\_\_\_\_ or \_\_\_\_\_ of the method call.
  - e. If there are more recursive or nested method calls than can be stored on the program execution stack, an error known as a(n) \_\_\_\_\_ occurs.
  - f. Iteration normally uses a repetition statement, whereas recursion normally uses a(n) \_\_\_\_\_ statement.
  - g. Fractals have a(n) \_\_\_\_\_ property; when subdivided into parts, each is a reduced-size copy of the whole.
- 

[Page 780]

- h. The \_\_\_\_\_ of a string are all the different strings that can be created by rearranging the characters of the original string.
- i. The program execution stack is also referred to as the \_\_\_\_\_ stack.

## Answers to Self-Review Exercises

[15.1](#) a) False. A method that calls itself indirectly is an example of recursion more specifically, an example of indirect recursion. b) False. Recursion can be inefficient in computation because of multiple method calls and memory space usage. c) True. d) False. To make recursion feasible, the recursion step in a recursive solution must resemble the original problem, but be a slightly *smaller* version of it.

[15.2](#) d

[15.3](#) a

[15.4](#) c

[15.5](#) b

[15.6](#) a) golden ratio, golden mean. b) top. c) last-in, first-out (LIFO). d) activation record, stack frame. e) stack overflow. f) selection. g) self-similar. h) permutations. i) method-call.

## Exercises

15.7 What does the following code do?

```

1 public int mystery(int a, int b)
2 {
3 if (b == 1)
4 return a;
5 else
6 return a + mystery(a, b - 1);
7 } // end method mystery

```

15.8 Find the error(s) in the following recursive method, and explain how to correct it (them). This method should find the sum of the values from 0 to *n*.

```

1 public int sum(int n)
2 {
3 if (n == 0)
4 return 0;
5 else
6 return n + sum(n);
7 } // end method sum

```

15.9 (*Recursive power Method*) Write a recursive method `power( base, exponent )` that, when called, returns

$base^{exponent}$

For example, `power( 3,4 ) = 3 * 3 * 3 * 3`. Assume that `exponent` is an integer greater than or equal to 1. [*Hint:* The recursion step should use the relationship

---

[Page 781]

$base^{exponent} = base \cdot base^{exponent-1}$

and the terminating condition occurs when `exponent` is equal to 1, because

$base^1 = base$

Incorporate this method into a program that enables the user to enter the `base` and `exponent`.]

15.10 (*Visualizing Recursion*) It is interesting to watch recursion "in action." Modify the factorial method in [Fig. 15.3](#) to print its local variable and recursive-call parameter. For each recursive call, display the outputs on a separate line, and add a level of indentation. Do your utmost to make the outputs clear, interesting and meaningful. Your goal here is to design and implement an output format that makes it easier to understand recursion. You may want to add such

display capabilities to other recursion examples and exercises throughout the text.

15.11 (*Greatest Common Divisor*) The greatest common divisor of integers  $x$  and  $y$  is the largest integer that evenly divides into both  $x$  and  $y$ . Write a recursive method `gcd` that returns the greatest common divisor of  $x$  and  $y$ . The `gcd` of  $x$  and  $y$  is defined recursively as follows: If  $y$  is equal to 0, then `gcd( x, y )` is  $x$ ; otherwise, `gcd( x, y )` is `gcd( y, x % y )`, where `%` is the remainder operator. Use this method to replace the one you wrote in the application of [Exercise 6.27](#).

15.12 What does the following program do?

```
1 // Exercise 15.12 Solution: MysteryClass.java
2
3 public class MysteryClass
4 {
5 public int mystery(int array2[], int size)
6 {
7 if (size == 1)
8 return array2[0];
9 else
10 return array2[size - 1] + mystery(array2, size - 1);
11 } // end method mystery
12 } // end class MysteryClass
```

```
1 // Exercise 15.12 Solution: MysteryTest.java
2
3 public class MysteryTest
4 {
5 public static void main(String args[])
6 {
7 MysteryClass mysteryObject = new MysteryClass();
8
9 int array[] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
10
11 int result = mysteryObject.mystery(array, array.length);
12
13 System.out.printf("Result is: %d\n", result);
14 } // end method main
15 } // end class MysteryTest
```

15.13 What does the following program do?

```
1 // Exercise 15.13 Solution: SomeClass.java
2
3 public class SomeClass
4 {
5 public String someMethod(
6 int array2[], int x, String output)
7 {
8 if (x < array2.length)
9 return String.format(
```

```

10 "%s%d ", someMethod(array2, x + 1), array2[x]);
11 else
12 return "";
13 } // end method someMethod
14 } // end class SomeClass

```

```

1 // Exercise 15.13 Solution: SomeClassTest.java
2
3 public class SomeClassTest
4 {
5 public static void main(String args[])
6 {
7 SomeClass someClassObject = new SomeClass();
8
9 int array[] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
10
11 String results =
12 someClassObject.someMethod(array, 0);
13
14 System.out.println(results);
15 } // end main
16 } // end class SomeClassTest

```

- 15.14 (*Palindromes*) A palindrome is a string that is spelled the same way forwards and backwards. Some examples of palindromes are "radar," "able was i ere i saw elba" and (if spaces are ignored) "a man a plan a canal panama." Write a recursive method `testPalindrome` that returns `boolean` value `true` if the string stored in the array is a palindrome and `false` otherwise. The method should ignore spaces and punctuation in the string.
- 15.15 (*Eight Queens*) A puzzler for chess buffs is the Eight Queens problem, which asks the following: Is it possible to place eight queens on an empty chessboard so that no queen is "attacking" any other (i.e., no two queens are in the same row, in the same column or along the same diagonal)? For instance, if a queen is placed in the upper-left corner of the board, no other queens could be placed in any of the marked squares shown in [Fig. 15.25](#). Solve the problem recursively. [*Hint:* Your solution should begin with the first column and look for a location in that column where a queen can be placed initially, place the queen in the first row. The solution should then recursively search the remaining columns. In the first few columns, there will be several locations where a queen may be placed. Take the first available location. If a column is reached with no possible location for a queen, the program should return to the previous column, and move the queen in that column to a new row. This continuous backing up and trying new alternatives is an example of recursive backtracking.]

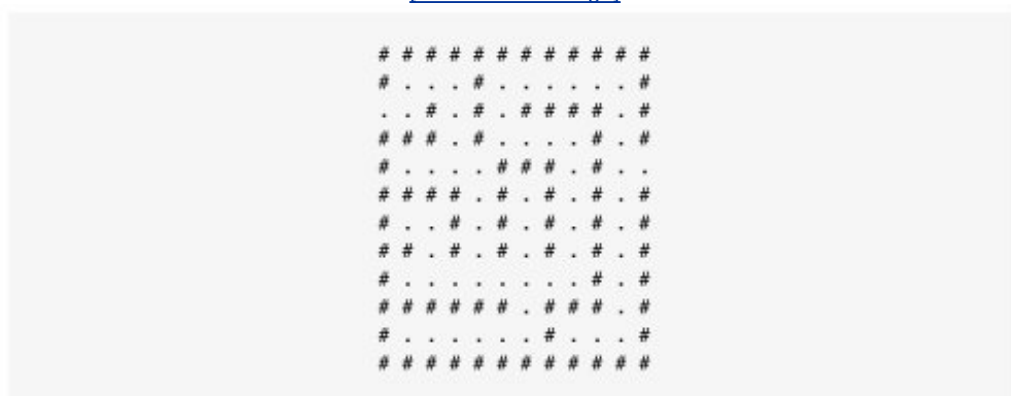

Figure 15.25. Squares eliminated by placing a queen in the upper-left corner of a chessboard.

- 15.16 (*Print an Array*) Write a recursive method `printArray` that displays all the elements in an array of integers, separated by spaces.
- 15.17 (*Print an Array Backwards*) Write a recursive method `stringReverse` that takes a character array containing a string as an argument and prints the string backwards. [Hint: Use `String` method `toCharArray`, which takes no arguments, to get a `char` array containing the characters in the `String`.]
- 15.18 (*Find the Minimum Value in an Array*) Write a recursive method `recursiveMinimum` that determines the smallest element in an array of integers. The method should return when it receives an array of one element.
- 15.19 (*Fractals*) Repeat the fractal pattern in [Section 15.9](#) to form a star. Begin with five lines, instead of one, where each line is a different arm of the star. Apply the "Lo fractal" pattern to each arm of the star.
- 15.20 (*Maze Traversal Using Recursive Backtracking*) The grid of `#s` and dots (`.`) in [Fig. 15.26](#) is a two-dimensional array representation of a maze. The `#s` represent the walls of the maze, and the dots represent locations in the possible paths through the maze. Moves can be made only to a location in the array that contains a dot.

Figure 15.26. Two-dimensional array representation of a maze.

[\[View full size image\]](#)

Write a recursive method (`mazeTraversal`) to walk through mazes like the one in [Fig. 15.26](#). The method should receive as arguments a 12-by-12 character array representing the maze and the current location in the maze (the first time this method is called, the current location should be the entry point of the maze). As `mazeTraversal` attempts to locate the exit, it should place the character `x` in each square in the path. There is a simple algorithm for walking

through a maze that guarantees finding the exit (assuming there is an exit). If there is no exit, you will arrive at the starting location again. The algorithm for this method is as follows: From the current location in the maze, try to move one space in any of the possible directions (down, right, up or left). If it is possible to move in at least one direction, call `mazeTraversal` recursively, passing the new spot on the maze as the current spot. If it is not possible to go in any directions, "back up" to a previous location in the maze and try a new direction for that location. Program the method to display the maze after each move so the user can watch as the maze is solved. The final output of the maze should display only the path needed to solve the maze. If going in a particular direction results in a dead end, the `x`'s going in that direction should not be displayed. [*Hint:* To display only the final path, it may be helpful to mark off spots that result in a dead end with another character (such as `'0'`).]

---

[Page 784]

- 15.21 (*Generating Mazes Randomly*) Write a method `mazeGenerator` that takes as an argument a two-dimensional 12-by-12 character array and randomly produces a maze. The method should also provide the starting and ending locations of the maze. Test your method `mazeTraversal` from [Exercise 15.20](#), using several randomly generated mazes.
- 15.22 (*Mazes of Any Size*) Generalize methods `mazeTraversal` and `mazeGenerator` of [Exercise 15.20](#) and [Exercise 15.21](#) to process mazes of any width and height.
- 15.23 (*Time to Calculate Fibonacci Numbers*) Enhance the Fibonacci program of [Fig. 15.5](#) so that it calculates the approximate amount of time required to perform the calculation and the number of calls made to the recursive method. For this purpose, call `static System` method `currentTimeMillis`, which takes no arguments and returns the computer's current time in milliseconds. Call this method twice: once before the call to `fibonacci` and once after the call to `fibonacci`. Save each of these values and calculate the difference in the times to determine how many milliseconds were required to perform the calculation. Then, add a variable to the `FibonacciCalculator` class, and use this variable to determine the number of calls made to method `fibonacci`. Display your results.

*With sobs and tears he sorted out*

*Those of the largest size ...*

Lewis Carroll

*Attempt the end, and never stand to doubt;*

*Nothing's so hard, but search will find it out.*

Robert Herrick

*'Tis in my memory lock'd, And you yourself shall keep the key of it.*

William Shakespeare

*It is an immutable law in business that words are words, explanations are explanations, promises are promises but only performance is reality.*

Harold S. Green

## OBJECTIVES

In this chapter you will learn:

- To search for a given value in an array using linear search and binary search.
- To sort arrays using the iterative selection and insertion sort algorithms.
- To sort arrays using the recursive merge sort algorithm.
- To determine the efficiency of searching and sorting algorithms.

## 16.1. Introduction

**Searching** data involves determining whether a value (referred to as the **search key**) is present in the data and, if so, finding the value's location. Two popular search algorithms are the simple linear search and the faster but more complex binary search. **Sorting** places data in order, typically ascending or descending, based on one or more **sort keys**. A list of names could be sorted alphabetically, bank accounts could be sorted by account number, employee payroll records could be sorted by social security number, and so on. This chapter introduces two simple sorting algorithms, the selection sort and the insertion sort, along with the more efficient but more complex merge sort. [Figure 16.1](#) summarizes the searching and sorting algorithms discussed in this book.

## 16.2. Searching Algorithms

Looking up a phone number, accessing a Web site and checking the definition of a word in a dictionary all involve searching large amounts of data. The next two sections discuss two common search algorithmsone that is easy to program yet relatively inefficient and one that is relatively efficient but more complex and difficult to program.

### 16.2.1. Linear Search

The [linear search algorithm](#) searches each element in an array sequentially. If the search key does not match an element in the array, the algorithm tests each element, and when the end of the array is reached, informs the user that the search key is not present. If the search key is in the array, the algorithm tests each element until it finds one that matches the search key and returns the index of that element.

As an example, consider an array containing the following values

34 56 2 10 77 51 93 30 5 52

and a program that is searching for 51. Using the linear search algorithm, the program first checks whether 34 matches the search key. It does not, so the algorithm checks whether 56 matches the search key. The program continues moving through the array sequentially, testing 2, then 10, then 77. When the program tests 51, which matches the search key, the program returns the index 5, which is the location of 51 in the array. If, after checking every array element, the program determines that the search key does not match any element in the array, the program returns a sentinel value (e.g. -1).

[Figure 16.2](#) declares the `LinearArray` class. This class has two `private` instance variablesan array of `ints` named `data`, and a `static Random` object to fill the array with randomly generated `ints`. When an object of class `LinearArray` is instantiated, the constructor (lines 1219) creates and initializes the array `data` with random `ints` in the range 1099. If there are duplicate values in the array, linear search returns the index of the first element in the array that matches the search key.

Figure 16.2. `LinearArray` class.

(This item is displayed on page 788 in the print version)

```

1 // Fig 16.2: LinearArray.java
2 // Class that contains an array of random integers and a method
3 // that will search that array sequentially
4 import java.util.Random;
5
6 public class LinearArray
7 {
8 private int [] data; // array of values
9 private static Random generator = new Random();
10
11 // create array of given size and fill with random numbers
12 public LinearArray(int size)
13 {
14 data = new int [size]; // create space for array
15
16 // fill array with random ints in range 10-99
17 for (int i = 0 ; i < size; i++)
18 data[i] = 10 + generator.nextInt(90);
19 } // end LinearArray constructor
20
21 // perform a linear search on the data
22 public int linearSearch(int searchKey)
23 {
24 // loop through array sequentially
25 for (int index = 0 ; index < data.length; index++)
26 if (data[index] == searchKey)
27 return index; // return index of integer
28
29 return -1; // integer was not found
30 } // end method linearSearch
31
32 // method to output values in array
33 public String toString()
34 {
35 StringBuffer temporary = new StringBuffer();
36
37 // iterate through array
38 for (int element : data)
39 temporary.append(element + " ");
40
41 temporary.append("\n"); // add newline character
42 return temporary.toString();
43 } // end method toString
44 } // end class LinearArray

```

Lines 22-30 perform the linear search. The search key is passed to parameter `searchKey`. Lines 25-27 loop through the elements in the array. Line 26 compares each element in the array with `searchKey`. If the values are equal, line 27 returns the index of the element. If the loop ends without finding the value, line 29 returns `-1`. Lines 33-43 declare method `toString`, which returns a `String` representation of the array for printing.

[Figure 16.3](#) creates a `LinearArray` object containing an array of 10 `ints` (line 16) and allows the user to search the array for specific elements. Lines 22-23 prompt the user for the search key and store it in `searchInt`. Lines 25-41 then loop until the `searchInt` is equal to `-1`. The array holds ints from 10-99 (line 18 of [Fig. 16.2](#)). Line 28 calls method `linearSearch` to determine whether `searchInt` is in the array. If `searchInt` is not in the array, `linearSearch` returns `-1` and the program notifies the user (lines 31-32). If `searchInt` is in the array, `linearSearch` returns the position of the element, which the program outputs in lines 34-35. Lines

Figure 16.3. **LinearSearchTest** class.

## Efficiency of Linear Search

Searching algorithms all accomplish the same goal finding an element that matches a given search key, if such an element does, in fact, exist. There are, however, a number of things that differentiate search algorithms from another. The major difference is the amount of effort they require to complete the search. One way to describe this effort is with **Big O notation**, which indicates the worst-case run time for an algorithm, that is, how hard an algorithm may have to work to solve a problem. For searching and sorting algorithms, this is particularly dependent on how many data elements there are.

---

[Page 789]

Suppose an algorithm is designed to test whether the first element of an array is equal to the second element of the array. If the array has 10 elements, this algorithm requires one comparison. If the array has 1,000 elements, the algorithm still requires one comparison. In fact, the algorithm is completely independent of the number of elements in the array. This algorithm is said to have a **constant run time**, which is represented in Big O notation as  $O(1)$ . An algorithm that is  $O(1)$  does not necessarily require only one comparison.  $O(1)$  just means that the number of comparisons is *constant* it does not grow as the size of the array increases. An algorithm that tests whether the first element of an array is equal to any of the next three elements is still  $O(1)$  even though it requires three comparisons.

---

[Page 790]

An algorithm that tests whether the first element of an array is equal to *any* of the other elements of the array will require at most  $n-1$  comparisons, where  $n$  is the number of elements in the array. If the array has 10 elements, this algorithm requires up to nine comparisons. If the array has 1,000 elements, this algorithm requires up to 999 comparisons. As  $n$  grows larger, the  $n$  part of the expression "dominates" and subtracting one becomes inconsequential. Big O is designed to highlight these dominant terms and ignore terms that become unimportant as  $n$  grows. For this reason, an algorithm that requires a total of  $n-1$  comparisons (such as the one we described earlier) is said to be  $O(n)$ . An  $O(n)$  algorithm is referred to as having a **linear run time**.  $O(n)$  is often pronounced "on the order of  $n$ " or more simply "order  $n$ ."

Now suppose you have an algorithm that tests whether *any* element of an array is duplicated elsewhere in the array. The first element must be compared with every other element in the array. The second element must be compared with every other element except the first (it was already compared to the first). The third element must be compared with every other element except the first two. In the end, this algorithm will end up making  $(n-1) + (n-2) + \dots + 2 + 1$  or  $n^2/2 - n/2$  comparisons. As  $n$  increases, the  $n^2$  term dominates and the  $n$  term becomes inconsequential. Again, Big O notation highlights the  $n^2$  term, leaving  $n^2/2$ . But as we will soon see, constant factors are omitted in Big O notation.

Big O is concerned with how an algorithm's run time grows in relation to the number of items processed. Suppose an algorithm requires  $n^2$  comparisons. With four elements, the algorithm will require 16 comparisons; with eight elements, the algorithm will require 64 comparisons. With this algorithm, doubling the number of elements quadruples the number of comparisons. Consider a similar algorithm requiring  $n^2/2$  comparisons. With four elements, the algorithm will require eight comparisons; with eight elements, the algorithm will require 32 comparisons. Again, doubling the number of elements quadruples the number of comparisons. Both of these algorithms grow as the square of  $n$ , so Big O ignores the constant and both algorithms are considered to be  $O(n^2)$ , which is referred to as **quadratic run time** and pronounced "on the order of  $n$ -squared" or more simply "order  $n$ -squared."

---

[Page 791]

When  $n$  is small,  $O(n^2)$  algorithms (running on today's billion-operation-per-second personal computers) will not noticeably affect performance. But as  $n$  grows you will start to notice the performance degradation. An  $O(n^2)$  algorithm running on a million-element array would require a trillion "operations" (where each could actually require several machine instructions to execute). This could require a few hours to execute. A billion-element array would require a quintillion operations, a number so large that the algorithm could take decades!  $O(n^2)$  algorithms, unfortunately, are easy to write, as you will see in this chapter. You will also see algorithms with more favorable Big O measures. These efficient algorithms often take a bit more cleverness and work to create, but their superior performance can be well worth the extra effort, especially as  $n$  gets large and as algorithms are compounded into larger programs.

The linear search algorithm runs in  $O(n)$  time. The worst case in this algorithm is that every element must be checked to determine whether the search item exists in the array. If the size of the array is doubled, the number of comparisons that the algorithm must perform is also doubled. Note that linear search can provide outstanding performance if the element matching the search key happens to be at or near the front of the array. But we seek algorithms that perform well, on average, across all searches, including those where the element matching the search key is near the end of the array.

Linear search is the easiest search algorithm to program, but it can be slow compared to other search algorithms. If a program needs to perform many searches on large arrays, it may be better to implement a different, more efficient algorithm, such as the binary search which we present in the next section.

## Performance Tip 16.1

*Sometimes the simplest algorithms perform poorly. Their virtue is that they are easy to program, test and debug. Sometimes more complex algorithms are required to realize maximum performance.*

## 16.2.2. Binary Search

The **binary search algorithm** is more efficient than the linear search algorithm, but it requires that the array be sorted. The first iteration of this algorithm tests the middle element in the array. If this matches the search key, the algorithm ends. Assuming the array is sorted in ascending order, then if the search key is less than the middle element, the search key cannot match any element in the second half of the array and the algorithm continues with only the first half of the array (i.e., the first element up to, but not including the middle element). If the search key is greater than the middle element, the search key cannot match any element in the first half of the array and the algorithm continues with only the second half of the array (i.e., the element after the middle element through the last element). Each iteration tests the middle value of the remaining portion of the array. If the search key does not match the element, the algorithm eliminates half of the remaining elements. The algorithm ends either by finding an element that matches the search key or reducing the sub-array to zero size.

As an example consider the sorted 15-element array

2 3 5 10 27 30 34 51 56 65 77 81 82 93 99

---

[Page 792]

and a search key of 65. A program implementing the binary search algorithm would first check whether 51 is the search key (because 51 is the middle element of the array). The search key (65) is larger than 51, so 51 is discarded along with the first half of the array (all elements smaller than 51.) Next, the algorithm checks whether 81 (the middle element of the remainder of the array) matches the search key. The search key (65) is smaller than 81, so 81 is discarded along with the elements larger than 81. After just two tests, the algorithm has narrowed the number of values to check to three (56, 65 and 77). The algorithm then checks 65 (which indeed matches the search key), and returns the index of the array element containing 65. This algorithm required just three comparisons to determine whether the search key matched an element of the array. Using a linear search algorithm would have required 10 comparisons. [*Note:* In this example, we have chosen to use an array with 15 elements so that there will always be an obvious middle element in the array. With an even number of elements, the middle of the array lies between two elements. We implement the algorithm to chose the lower of those two elements.]

[Figure 16.4](#) declares class `BinaryArray`. This class is similar to `LinearArray` it has two `private` instance variables, a constructor, a search method (`binarySearch`), a `remainingElements` method and a `toString` method. Lines 1322 declare the constructor. After initializing the array with random `ints` from 1099 (lines 1819), line 21 calls the `Arrays.sort` method on the array `data`. Method `sort` is a `static` method of class `Arrays` that sorts the elements in an array in ascending order. Recall that the binary search algorithm will work only on a sorted array.

Figure 16.4. `BinaryArray` class.

(This item is displayed on pages 792 - 793 in the print version)

```
1 // Fig 16.4: BinaryArray.java
2 // Class that contains an array of random integers and a method
3 // that uses binary search to find an integer.
4 import java.util.Random;
5 import java.util.Arrays;
6
7 public class BinaryArray
8 {
9 private int [] data; // array of values
10 private static Random generator = new Random();
11
12 // create array of given size and fill with random integers
13 public BinaryArray(int size)
14 {
15 data = new int [size]; // create space for array
16
17 // fill array with random ints in range 10-99
18 for (int i = 0; i < size; i++)
19 data[i] = 10 + generator.nextInt(90);
20 }
```

```

21 Arrays.sort(data);
22 } // end BinaryArray constructor
23
24 // perform a binary search on the data
25 public int binarySearch(int searchElement)
26 {
27 int low = 0 ; // low end of the search area
28 int high = data.length - 1 ; // high end of the search area
29 int middle = (low + high + 1) / 2 ; // middle element
30 int location = -1; // return value; -1 if not found
31
32 do // loop to search for element
33 {
34 // print remaining elements of array
35 System.out.print(remainingElements(low, high));
36
37 // output spaces for alignment
38 for (int i = 0; i < middle; i++)
39 System.out.print(" ");
40 System.out.println(" * "); // indicate current middle
41
42 // if the element is found at the middle
43 if (searchElement == data[middle])
44 location = middle; // location is the current middle
45
46 // middle element is too high
47 else if (searchElement < data[middle])
48 high = middle - 1 ; // eliminate the higher half
49 else // middle element is too low
50 low = middle + 1 ; // eliminate the lower half
51
52 middle = (low + high + 1) / 2 ; // recalculate the middle
53 } while ((low <= high) && (location == -1));
54
55 return location; // return location of search key
56 } // end method binarySearch
57
58 // method to output certain values in array
59 public String remainingElements(int low, int high)
60 {
61 StringBuffer temporary = new StringBuffer();
62
63 // output spaces for alignment
64 for (int i = 0; i < low; i++)
65 temporary.append(" ");
66
67 // output elements left in array
68 for (int i = low; i <= high; i++)
69 temporary.append(data[i] + " ");
70
71 temporary.append("\n");
72 return temporary.toString();
73 } // end method remainingElements
74
75 // method to output values in array
76 public String toString()
77 {
78 return remainingElements(0, data.length - 1);
79 } // end method toString
80 } // end class BinaryArray

```

Lines 2556 declare method `binarySearch`. The search key is passed into parameter `searchElement` (line 25). Lines 2729 calculate the `low` end index, `high` end index and `middle` index of the portion of the array that the program is currently searching. At the beginning of the method, the `low` end is 0, the `high` end is the length of the array minus 1 and the `middle` is the average of these two values. Line 30 initializes the `location` of the element to -1 the value that will be returned if the element is not found. Lines 3253 loop until `low` is greater than `high` (this occurs when the element is not found) or `location` does not equal -1 (indicating that the search key was found). Line 43 tests whether the value in the `middle` element is equal to `searchElement`. If this is `TRUE`, line 44 assigns `middle` to `location`. Then the loop terminates and `location` is returned to the caller. Each iteration of the loop tests a single value (line 43) and eliminates half of the remaining values in the array (line 48 or 50).

Lines 2644 of [Fig. 16.5](#) loop until the user enters -1. For each other number the user enters, the program performs a binary search on the data to determine whether it matches an element in the array. The first line of output from this program is the array of `ints`, in increasing order. When the user instructs the program to search for 23, the program first tests the middle element, which is 42 (as indicated by \*). The search key is less than 42, so the program eliminates the second half of the array and tests the middle element from the first half of the array. The search key is smaller than 34, so the program eliminates the second half of the array, leaving only three elements. Finally, the program checks 23 (which matches the search key) and returns the index 1.

## Efficiency of Binary Search

In the worst-case scenario, searching a sorted array of 1,023 elements will take only 10 comparisons when using a binary search. Repeatedly dividing 1,023 by 2 (because after each comparison, we are able to eliminate half of the array) and rounding down (because we also remove the middle element) yields the values 511, 255, 127, 63, 31, 15, 7, 3, 1 and 0. The number 1023 ( $2^{10} - 1$ ) is divided by 2 only 10 times to get the value 0, which indicates that there are no more elements to test. Dividing by 2 is equivalent to one comparison in the binary-search algorithm. Thus, an array of 1,048,575 ( $2^{20} - 1$ ) elements takes a maximum of 20 comparisons to find the key, and an array of over one billion elements takes a maximum of 30 comparisons to find the key. This is a tremendous improvement in performance over the linear search. For a one-billion-element array, this is a difference between an average of 500 million comparisons for the linear search and a maximum of only 30 comparisons for the binary search! The maximum number of comparisons needed for the binary search of any sorted array is the exponent of the first power of 2 greater than the number of elements in the array which is represented as  $\log_2 n$ . All logarithms grow at roughly the same rate, so in big O notation the base can be omitted. This results in a big O of  $O(\log n)$  for a binary search which is also known as **logarithmic run time**.

[< PREV](#)[NEXT >](#)

## 16.3. Sorting Algorithms

Sorting data (i.e., placing the data into some particular order, such as ascending or descending) is one of the most important computing applications. A bank sorts all checks by account number so that it can prepare individual bank statements at the end of each month. Telephone companies sort their lists of accounts by last name and, further, by first name to make it easy to find phone numbers. Virtually every organization must sort some data, and often, massive amounts of it. Sorting data is an intriguing, computer-intensive problem that has attracted intense research efforts.

An important item to understand about sorting is that the end result the sorted array will be the same no matter which algorithm you use to sort the array. The choice of algorithm affects only the run time and memory use of the program. The rest of the chapter introduces three common sorting algorithms. The first two selection sort and insertion sort are simple algorithms to program, but are inefficient. The last algorithm merge sort is a much faster algorithm than selection sort and insertion sort, but is harder to program. We focus on sorting arrays of primitive type data, namely ints. It is possible to sort arrays of objects of classes as well. We discuss this in [Section 19.6.1](#).

### 16.3.1. Selection Sort

**Selection sort** is a simple, but inefficient, sorting algorithm. The first iteration of the algorithm selects the smallest element in the array and swaps it with the first element. The second iteration selects the second-smallest item (which is the smallest item of the remaining elements) and swaps it with the second element. The algorithm continues until the last iteration selects the second-largest element and swaps it with the second-to-last index, leaving the largest element in the last index. After the  $i$ th iteration, the smallest  $i$  items of the array will be sorted into increasing order in the first  $i$  elements of the array.

---

[Page 797]

As an example, consider the array

34 56 4 10 77 51 93 30 5 52

A program that implements selection sort first determines the smallest element (4) of this array which is contained in index 2. The program swaps 4 with 34, resulting in

4 56 34 10 77 51 93 30 5 52

The program then determines the smallest value of the remaining elements (all elements except 4), which is 5, contained in index 8. The program swaps 5 with 56, resulting in

4 5 34 10 77 51 93 30 56 52

On the third iteration, the program determines the next smallest value (10) and swaps it with 34.

4 5 10 34 77 51 93 30 56 52

The process continues until the array is fully sorted.

4 5 10 30 34 51 52 56 77 93

Note that after the first iteration, the smallest element is in the first position. After the second iteration, the two smallest elements are in order in the first two positions. After the third iteration, the three smallest elements are in order in the first three positions.

[Figure 16.6](#) declares the `SelectionSort` class. This class has two `private` instance variables an array of `int`s named `data`, and a `static Random` object to generate random integers to fill the array. When an object of class `SelectionSort` is instantiated, the constructor (lines 12-19) creates and initializes the array `data` with random `ints` in the range 10-99.

Figure 16.6. `SelectionSort` class.

(This item is displayed on pages 798 - 799 in the print version)

```
1 // Fig 16.6: SelectionSort.java
2 // Class that creates an array filled with random integers.
3 // Provides a method to sort the array with selection sort.
4 import java.util.Random;
5
6 public class SelectionSort
7 {
8 private int [] data; // array of values
9 private static Random generator = new Random();
10
11 // create array of given size and fill with random integers
12 public SelectionSort(int size)
13 {
14 data = new int [size]; // create space for array
15
16 // fill array with random ints in range 10-99
17 for (int i = 0; i < size; i++)
18 data[i] = 10 + generator.nextInt(90);
19 } // end SelectionSort constructor
20
21 // sort array using selection sort
22 public void sort()
23 {
24 int smallest; // index of smallest element
25
26 // loop over data.length - 1 elements
27 for (int i = 0 ; i < data.length - 1 ; i++)
28 {
29 smallest = i; // first index of remaining array
30
31 // loop to find index of smallest element
32 for (int index = i + 1 ; index < data.length; index++)
33 if (data[index] < data[smallest])
```

```

34 smallest = index;
35
36 swap(i, smallest); // swap smallest element into position
37 printPass(i + 1, smallest); // output pass of algorithm
38 } // end outer for
39 } // end method sort
40
41 // helper method to swap values in two elements
42 public void swap(int first, int second)
43 {
44 int temporary = data[first]; // store first in temporary
45 data[first] = data[second]; // replace first with second
46 data[second] = temporary; // put temporary in second
47 } // end method swap
48
49 // print a pass of the algorithm
50 public void printPass(int pass, int index)
51 {
52 System.out.print(String.format("after pass %2d: ", pass));
53
54 // output elements till selected item
55 for (int i = 0 ; i < index; i++)
56 System.out.print(data[i] + " ");
57
58 System.out.print(data[index] + "* "); // indicate swap
59
60 // finish outputting array
61 for (int i = index + 1; i < data.length; i++)
62 System.out.print(data[i] + " ");
63
64 System.out.print("\n"); // for alignment
65
66 // indicate amount of array that is sorted
67 for (int j = 0 ; j < pass; j++)
68 System.out.print("-- ");
69 System.out.println("\n"); // add newline
70 } // end method indicateSelection
71
72 // method to output values in array
73 public String toString()
74 {
75 StringBuffer temporary = new StringBuffer();
76
77 // iterate through array
78 for (int element : data)
79 temporary.append(element + " ");
80
81 temporary.append("\n"); // add newline character
82 return temporary.toString();
83 } // end method toString
84 } // end class SelectionSort

```

Lines 22-39 declare the `sort` method. Line 24 declares the variable `smallest`, which will store the index of the smallest element in the remaining array. Lines 27-38 loop `data.length - 1` times. Line 29 initializes the index of the smallest element to the current item. Lines 32-34 loop over the remaining elements in the array. For each of these elements, line 33 compares its value to the value of the smallest element. If the current element is smaller than the smallest element, line 34 assigns the current element's index to `smallest`. When this loop finishes, `smallest` will contain the index of the smallest element in the remaining array. Line 36

calls method `swap` (lines 4247) to place the smallest remaining element in the next spot in the array.

Line 9 of [Fig. 16.7](#) creates a `SelectionSort` object with 10 elements. Line 12 implicitly call method `toString` to output the unsorted object. Line 14 calls method `sort` (lines 2239 of [Fig. 16.6](#)), which sorts the elements using selection sort. Then lines 1617 output the sorted object. The output of this program uses dashes to indicate the portion of the array that is sorted after each pass. An asterisk is placed next to the position of the element that was swapped with the smallest element on that pass. On each pass, the element next to the asterisk and the element above the rightmost set of dashes were the two values that were swapped.

[Page 799]

## Efficiency of Selection Sort

The selection sort algorithm runs in  $O(n^2)$  time. The sort method in lines 2239 of [Fig. 16.6](#), which implements the selection sort algorithm, contains two `for` loops. The outer `for` loop (lines 2738) iterates over the first  $n-1$  elements in the array, swapping the smallest remaining item into its sorted position. The inner `for` loop (lines 3234) iterates over each item in the remaining array, searching for the smallest element. This loop executes  $n-1$  times during the first iteration of the outer loop,  $n-2$  times during the second iteration, then  $n-3$ , ..., 3, 2, 1. This inner loop will iterate a total of  $n(n-1)/2$  or  $(n^2 - n)/2$ . In Big O notation, smaller terms drop out and constants are ignored, leaving a final Big O of  $O(n^2)$ .

---

[Page 800]

### 16.3.2. Insertion Sort

[Insertion sort](#) is another simple, but inefficient, sorting algorithm. The first iteration of this algorithm takes the second element in the array and, if it is less than the first element, swaps it with the first element. The second iteration looks at the third element and inserts it into the correct position with respect to the first two elements, so all three elements are in order. At the  $i$ th iteration of this algorithm, the first  $i$  elements in the original array will be sorted.

---

[Page 801]

Consider as an example the following array [*Note:* This array is identical to the array used in the discussions of selection sort and merge sort.]

```
34 56 4 10 77 51 93 30 5 52
```

A program that implements the insertion sort algorithm will first look at the first two elements of the array, 34 and 56. These two elements are already in order, so the program continues (if they were out of order, the program would swap them).

In the next iteration, the program looks at the third value, 4. This value is less than 56, so the program stores 4 in a temporary variable and moves 56 one element to the right. The program then checks and determines that 4 is less than 34, so it moves 34 one element to the right. The program has now reached the beginning of the array, so it places 4 in the zeroth element. The array now is

4 34 56 10 77 51 93 30 5 52

In the next iteration, the program stores the value 10 in a temporary variable. Then the program compares 10 to 56 and moves 56 one element to the right because it is larger than 10. The program then compares 10 to 34, moving 34 right one element. When the program compares 10 to 4, it observes that 10 is larger than 4 and places 10 in element 1. The array now is

4 10 34 56 77 51 93 30 5 52

Using this algorithm, at the  $k$ th iteration, the first  $k$  elements of the original array are sorted. They may not be in their final locations, however, because smaller values may be located later in the array.

[Figure 16.8](#) declares the `InsertionSort` class. Lines 22-46 declare the `sort` method. Line 24 declares the variable `insert`, which holds the element you are going to insert while you move the other elements. Lines 27-45 loop over `data.length - 1` items in the array. In each iteration, line 30 stores in `insert` the value of the element that will be inserted into the sorted portion of the array. Line 33 declares and initializes the variable `moveItem`, which keeps track of where to insert the element. Lines 36-41 loop to locate the correct position where the element should be inserted. The loop will terminate either when the program reaches the front of the array or when it reaches an element that is less than the value to be inserted. Line 39 moves an element to the right, and line 40 decrements the position at which to insert the next element. After the loop ends, line 43 inserts the element into place. [Figure 16.9](#) is the same as [Fig. 16.7](#) except that it creates and uses an `InsertionSort` object. The output of this program uses dashes to indicate the portion of the array that is sorted after each pass. An asterisk is placed next to the element that was inserted into place on that pass.

## Efficiency of Insertion Sort

The insertion sort algorithm also runs in  $O(n^2)$  time. Like selection sort, the implementation of insertion sort (lines 2246 of [Fig. 16.8](#)) contains two loops. The `for` loop (lines 2745) iterates `data.length - 1` times, inserting an element into the appropriate position in the elements sorted so far. For the purposes of this application, `data.length - 1` is equivalent to  $n - 1$  (as `data.length` is the size of the array). The `while` loop (lines 3641) iterates over the preceding elements in the array. In the worst case, this `while` loop will require  $n - 1$  comparisons. Each individual loop runs in  $O(n)$  time. In Big O notation, nested loops mean that you must multiply the number of comparisons. For each iteration of an outer loop, there will be a certain number of iterations of the inner loop. In this algorithm, for each  $O(n)$  iterations of the outer loop, there will be  $O(n)$  iterations of the inner loop. Multiplying these values results in a Big O of  $O(n^2)$ .

### 16.3.3. Merge Sort

[Merge sort](#) is an efficient sorting algorithm, but is conceptually more complex than selection sort and insertion sort. The merge sort algorithm sorts an array by splitting it into two equal-sized subarrays, sorting each subarray and then merging them into one larger array. With an odd number of elements, the algorithm creates the two subarrays such that one has one more element than the other.

---

[Page 805]

The implementation of merge sort in this example is recursive. The base case is an array with one element. A one-element array is, of course, sorted, so merge sort immediately returns when it is called with a one-element array. The recursion step splits an array into two approximately equal pieces, recursively sorts them and then merges the two sorted arrays into one larger, sorted array.

Suppose the algorithm has already merged smaller arrays to create sorted arrays A:

4   10   34   56   77

and B:

5   30   51   52   93

Merge sort combines these two arrays into one larger, sorted array. The smallest element in A is 4 (located in the zeroth index of A). The smallest element in B is 5 (located in the zeroth index of B). In order to determine the smallest element in the larger array, the algorithm compares 4 and 5. The value from A is smaller, so 4 becomes the first element in the merged array. The algorithm continues by comparing 10 (the second element in A) to 5 (the first element in B). The value from B is smaller, so 5 becomes the second element in the larger array. The algorithm continues by comparing 10 to 30, with 10 becoming the third element in the array, and so on.

Lines 2225 of [Fig. 16.10](#) declare the `sort` method. Line 24 calls method `sortArray` with `0` and `data.length - 1` as the arguments. The arguments correspond to the beginning and ending indices of the array to be sorted. These values tell method `sortArray` to operate on the entire array.

Figure 16.10. `MergeSort` class.

(This item is displayed on pages 805 - 807 in the print version)

```

34 int middle2 = middle1 + 1; // calculate next element over
35
36 // output split step
37 System.out.println("split: " + subarray(low, high));
38 System.out.println(" " + subarray(low, middle1));
39 System.out.println(" " + subarray(middle2, high));
40 System.out.println();
41
42 // split array in half; sort each half (recursive calls)
43 sortArray(low, middle1); // first half of array
44 sortArray(middle2, high); // second half of array
45
46 // merge two sorted arrays after split calls return
47 merge (low, middle1, middle2, high);
48 } // end if
49 } // end method split
50
```

```

51 // merge two sorted subarrays into one sorted subarray
52 private void merge(int left, int middle1, int middle2, int right)
53 {
54 int leftIndex = left; // index into left subarray
55 int rightIndex = middle2; // index into right subarray
56 int combinedIndex = left; // index into temporary working array
57 int [] combined = new int [data.length]; // working array
58
59 // output two subarrays before merging
60 System.out.println("merge: " + subarray(left, middle1));
61 System.out.println(" " + subarray(middle2, right));
62
63 // merge arrays until reaching end of either
64 while (leftIndex <= middle1 && rightIndex <= right)
65 {
66 // place smaller of two current elements into result
67 // and move to next space in arrays
68 if (data[leftIndex] <= data[rightIndex])
69 combined[combinedIndex++] = data[leftIndex++];
70 else
71 combined[combinedIndex++] = data[rightIndex++];
72 } // end while
73
74 // if left array is empty
75 if (leftIndex == middle2)
76 // copy in rest of right array
77 while (rightIndex <= right)
78 combined[combinedIndex++] = data[rightIndex++];
79 else // right array is empty
80 // copy in rest of left array
81 while (leftIndex <= middle1)
82 combined[combinedIndex++] = data[leftIndex++];
83
84 // copy values back into original array
85 for (int i = left; i <= right; i++)
86 data[i] = combined[i];
87
88 // output merged array
89 System.out.println(" " + subarray(left, right));
90 System.out.println();
91 } // end method merge
92
93 // method to output certain values in array
94 public String subarray(int low, int high)
95 {
96 StringBuffer temporary = new StringBuffer();
97
98 // output spaces for alignment
99 for (int i = 0; i < low; i++)
100 temporary.append(" ");
101
102 // output elements left in array
103 for (int i = low; i <= high; i++)
104 temporary.append(" " + data[i]);
105
106 return temporary.toString();
107 } // end method subarray
108
109 // method to output values in array
110 public String toString()
111 {

```

```
112 return subarray(0, data.length - 1);
113 } // end method toString
114 } // end class MergeSort
```

[Page 807]

Method `sortArray` is declared in lines 2849. Line 31 tests the base case. If the size of the array is `1`, the array is already sorted, so the method simply returns immediately. If the size of the array is greater than `1`, the method splits the array in two, recursively calls method `sortArray` to sort the two subarrays, then merges them. Line 43 recursively calls method `sortArray` on the first half of the array, and line 44 recursively calls method `sortArray` on the second half of the array. When these two method calls return, each half of the array has been sorted. Line 47 calls method `merge` (lines 5291) on the two halves of the array to combine the two sorted arrays into one larger sorted array.

[Page 808]

Lines 6472 in method `merge` loop until the program reaches the end of either subarray. Line 68 tests which element at the beginning of the arrays is smaller. If the element in the left array is smaller, line 69 places it in position in the combined array. If the element in the right array is smaller, line 71 places it in position in the combined array. When the `while` loop has completed (line 72), one entire subarray is placed in the combined array, but the other subarray still contains data. Line 75 tests whether the left array has reached the end. If so, lines 7778 fill the combined array with the elements of the right array. If the left array has not reached the end, then the right array must have reached the end, and lines 8182 fill the combined array with the elements of the left array. Finally, lines 8586 copy the combined array into the original array. [Figure 16.11](#) creates and uses a `MergeSort` object. The output from this program displays the splits and merges performed by merge sort, showing the progress of the sort at each step of the algorithm.

[Page 810]

## Efficiency of Merge Sort

Merge sort is a far more efficient algorithm than either insertion sort or selection sort. Consider the first (nonrecursive) call to method `sortArray`. This results in two recursive calls to method `sortArray` with subarrays each approximately half the size of the original array, and a single call to method `merge`. This call to method `merge` requires, at worst,  $n-1$  comparisons to fill the original array, which is  $O(n)$ . (Recall that each element in the array can be chosen by comparing one element from each of the subarrays.) The two calls to method `sortArray` result in four more recursive calls to method `sortArray`, each with a subarray approximately a quarter the size of the original array along with two calls to method `merge`. These two calls to method `merge` each require, at worst,  $n/2 - 1$  comparisons for a total number of comparisons of  $O(n)$ . This process continues, each call to `sortArray` generating two additional calls to `sortArray` and a call to `merge`, until the algorithm has split the array into one-element subarrays. At each level,  $O(n)$  comparisons are required to merge the subarrays. Each level splits the size of the arrays in half, so doubling the size of the array requires one more level. Quadrupling the size of the array requires two more levels. This pattern is logarithmic and results in  $\log_2 n$  levels. This results in a total efficiency of  $O(n \log n)$ . [Figure 16.12](#) summarizes many of the searching and sorting algorithms covered in this book and lists the Big O for each of them. [Figure 16.13](#) lists the Big O values we have covered in this chapter along with a number of values for  $n$  to highlight the differences in the growth rates.

Figure 16.12. Searching and sorting algorithms with Big O values.

## 16.4. Invariants

After writing an application, a programmer typically tests it thoroughly. Creating an exhaustive set of tests often is quite difficult, and it is always possible that a particular case remains untested. One technique that can help you test your programs thoroughly is to use invariants. An **invariant** is an assertion (see [Section 13.13](#)) that is true before and after the a portion of your code executes. Invariants are mathematical in nature and their concepts are more applicable to the theoretical side of computer science.

The most common type of invariant is a **loop invariant**. A loop invariant is an assertion that remains true

- before the execution of the loop,
- after every iteration of the loop body, and
- when the loop terminates.

A properly written loop invariant, can help you code a loop correctly. There are four steps to developing a loop from a loop invariant.

1. Set initial values for any loop control variables.
2. Determine the condition that causes the loop to terminate.
3. Modify the control variable(s) so the loop progresses toward termination.
4. Check that the invariant remains true at the end of each iteration.

As an example, we will examine method `linearSearch` from class `LinearArray` in [Fig. 16.2](#). The invariant for the linear search algorithm is:

```
for all k such that 0 <= k and k < index
 data[k] != searchKey
```

For example, suppose `index` equals 3. If we pick any non-negative number less than 3 such as 1 for the value of `k`, the element in `data` at location `k` in the array does not equal the `searchKey`. This invariant basically states that the portion of the array, called a **subarray**, from the start of the array up to but not including the element at `index` does not contain the `searchKey`. A subarray can have no elements, or it can encompass the entire array.

According to *Step 1*, we must first initialize control variable `index`. From the invariant, we see that if we set `index` to 0, then the subarray contains zero elements. Therefore, the invariant is true because a subarray with no elements cannot contain a value that matches the `searchKey`.

The second step is to determine the condition that causes the loop to terminate. The loop should end after searching the entire array when `index` equals the length of the array. In this case, no element of array `data` matches the `searchKey`. Once the `index` reaches the end of the array, the invariant remains true no elements

in the subarray (which in this case is the entire array) equal the `searchKey`.

For the loop to proceed to the next element, we increment control variable `index`. The last step is to ensure the invariant remains true after each iteration. The if statement (lines 2627 of [Fig. 16.2](#)) determines whether `data[ index ]` equals the `searchKey`. If so, the method finishes and returns `index`. Because `index` is the first occurrence of `searchKey` in `data`, the invariant is still true the subarray up to `index` does not contain the `searchKey`.

## 16.5. Wrap-up

This chapter introduced searching and sorting data. We discussed two searching algorithmslinear search and binary searchand three sorting algorithmsselection sort, insertion sort and merge sort. We also introduced Big-O notation, which helps you analyze the efficiency of an algorithm. You also learned about loop invariants, which must remain true before the loop begins executing, while the loop executes and when the loop terminates. In the next chapter, you will learn about dynamic data structures that can grow or shrink at execution time.

## Summary

- Searching data involves determining whether a search key is present in the data and, if so, finding its location.
- Sorting involves arranging data into order.
- The linear search algorithm searches each element in the array sequentially until it finds the correct element. If the element is not in the array, the algorithm tests each element in the array, and when the end of the array is reached, informs the user that the element is not present. If the element is in the array, linear search tests each item until it finds the correct item.
- A major difference among searching algorithms is the amount of effort they require in order to return a result.
- One way to describe the efficiency of an algorithm is with Big O notation ( $O$ ), which indicates how hard an algorithm may have to work to solve a problem.
- For searching and sorting algorithms, Big O is often dependent on how many elements are in the data.
- An algorithm that is  $O(1)$  does not necessarily require only one comparison. It just means that the number of comparisons does not grow as the size of the array increases.
- An  $O(n)$  algorithm is referred to as having a linear run time.
- Big O is designed to highlight dominant factors and ignore terms that become unimportant with high  $n$  values.
- Big O notation is concerned with the growth rate of algorithm run times, so constants are ignored.
- The linear search algorithm runs in  $O(n)$  time.
- The worst case in linear search is that every element must be checked to determine whether the search item exists. This occurs if the search key is the last element in the array or is not present.

---

[Page 813]

- The binary search algorithm is more efficient than the linear search algorithm, but it requires that the array be sorted.
- The first iteration of binary search tests the middle element in the array. If this is the search key, the algorithm returns its location. If the search key is less than the middle element, binary search continues with the first half of the array. If the search key is greater than the middle element, binary search continues with the second half of the array. Each iteration of binary search tests the middle value of the remaining array and, if the element is not found, eliminates half of the remaining elements.
- Binary search is a more efficient searching algorithm than linear search because binary search with each comparison eliminates from consideration half of the elements in the array.
- Binary search runs in  $O(\log n)$  time because each step removes half of the remaining elements.
- If the size of the array is doubled, binary search requires only one extra comparison to complete successfully.
- Selection sort is a simple, but inefficient, sorting algorithm.

- The first iteration of selection sort selects the smallest element in the array and swaps it with the first element. The second iteration of selection sort selects the second-smallest item (which is the smallest remaining item) and swaps it with the second element. Selection sort continues until the last iteration selects the second-largest element and swaps it with the second-to-last index, leaving the largest element in the last index. At the  $i$ th iteration of selection sort, the smallest  $i$  items of the whole array are sorted into the first  $i$  indices.
- The selection sort algorithm runs in  $O(n^2)$  time.
- The first iteration of insertion sort takes the second element in the array and, if it is less than the first element, swaps it with the first element. The second iteration of insertion sort looks at the third element and inserts it in the correct position with respect to the first two elements. After the  $i$ th iteration of insertion sort, the first  $i$  elements in the original array are sorted.
- The insertion sort algorithm runs in  $O(n^2)$  time.
- Merge sort is a sorting algorithm that is faster, but more complex to implement, than selection sort and insertion sort.
- The merge sort algorithm sorts an array by splitting the array into two equal-sized subarrays, sorting each subarray recursively and merging the subarrays into one larger array.
- Merge sort's base case is an array with one element. A one-element array is already sorted, so merge sort immediately returns when it is called with a one-element array. The merge part of merge sort takes two sorted arrays (these could be one-element arrays) and combines them into one larger sorted array.
- Merge sort performs the merge by looking at the first element in each array, which is also the smallest element in the array. Merge sort takes the smallest of these and places it in the first element of the larger array. If there are still elements in the subarray, merge sort looks at the second element in that subarray (which is now the smallest element remaining) and compares it to the first element in the other subarray. Merge sort continues this process until the larger array is filled.
- In the worst case, the first call to merge sort has to make  $O(n)$  comparisons to fill the  $n$  slots in the final array.
- The merging portion of the merge sort algorithm is performed on two subarrays, each of approximately size  $n/2$ . Creating each of these subarrays requires  $n/2 - 1$  comparisons for each subarray, or  $O(n)$  comparisons total. This pattern continues as each level works on twice as many arrays, but each is half the size of the previous array.
- Similar to binary search, this halving results in  $\log n$  levels for a total efficiency of  $O(n \log n)$ .

---

[Page 814]

- An invariant is an assertion that is true before and after the execution of a portion of your code.
- A loop invariant is an assertion that is true before you begin executing the loop, during each iteration of the loop and after the loop terminates.

## Self-Review Exercises

16.1 Fill in the blanks in each of the following statements:

- a. A selection sort application would take approximately \_\_\_\_\_ times as long to run on a 128-element array as on a 32-element array.
- b. The efficiency of merge sort is \_\_\_\_\_.

16.2 What key aspect of both the binary search and the merge sort accounts for the logarithmic portion of their respective Big Os?

16.3 In what sense is the insertion sort superior to the merge sort? In what sense is the merge sort superior to the insertion sort?

16.4 In the text, we say that after the merge sort splits the array into two subarrays, it then sorts these two subarrays and merges them. Why might someone be puzzled by our statement that "it then sorts these two subarrays"?

## Answers to Self-Review Exercises

- [16.1](#) a) 16, because an  $O(n^2)$  algorithm takes 16 times as long to sort four times as much information. b)  $O(n \log n)$ .
- [16.2](#) Both of these algorithms incorporate "halving" somehow reducing something by half. The binary search eliminates from consideration one half of the array after each comparison. The merge sort splits the array in half each time it is called.
- [16.3](#) The insertion sort is easier to understand and to program than the merge sort. The merge sort is far more efficient ( $O(n \log n)$ ) than the insertion sort ( $O(n^2)$ ).
- [16.4](#) In a sense, it does not really sort these two subarrays. It simply keeps splitting the original array in half until it provides a one-element subarray, which is, of course, sorted. It then builds up the original two subarrays by merging these one-element arrays to form larger subarrays which are then merged, and so on.

## Exercises

- 16.5 (*Bubble Sort*) Implement bubble sort, another simple yet inefficient sorting technique. It is called bubble sort or sinking sort because smaller values gradually "bubble" their way to the top of the array (i.e., toward the first element) like air bubbles rising in water, while the larger values sink to the bottom (end) of the array. The technique uses nested loops to make several passes through the array. Each pass compares successive pairs of elements. If a pair is in increasing order (or the values are equal), the bubble sort leaves the values as they are. If a pair is in decreasing order, the bubble sort swaps their values in the array.

---

[Page 815]

The first pass compares the first two elements of the array and swaps them if necessary. It then compares the second and third elements in the array. The end of this pass compares the last two elements in the array and swaps them if necessary. After one pass, the largest element will be in the last index. After two passes, the largest two elements will be in the last two indices. Explain why bubble sort is an  $O(n^2)$  algorithm.

- 16.6 (*Enhanced Bubble Sort*) Make the following simple modifications to improve the performance of the bubble sort you developed in [Exercise 16.5](#):
- After the first pass, the largest number is guaranteed to be in the highest-numbered element of the array; after the second pass, the two highest numbers are "in place"; and so on. Instead of making nine comparisons on every pass, modify the bubble sort to make eight comparisons on the second pass, seven on the third pass, and so on.
  - The data in the array may already be in the proper order or near-proper order, so why make nine passes if fewer will suffice? Modify the sort to check at the end of each pass whether any swaps have been made. If none have been made, the data must already be in the proper order, so the program should terminate. If swaps have been made, at least one more pass is needed.
- 16.7 (*Bucket Sort*) A bucket sort begins with a one-dimensional array of positive integers to be sorted and a two-dimensional array of integers with rows indexed from 0 to 9 and columns indexed from 0 to  $n-1$ , where  $n$  is the number of values to be sorted. Each row of the two-dimensional array is referred to as a *bucket*. Write a class named `BucketSort` containing a method called `sort` that operates as follows:
- Place each value of the one-dimensional array into a row of the bucket array, based on the value's "ones" (right-most) digit. For example, 97 is placed in row 7, 3 is placed in row 3 and 100 is placed in row 0. This procedure is called a *distribution pass*.
  - Loop through the bucket array row by row, and copy the values back to the original array. This procedure is called a *gathering pass*. The new order of the preceding values in the one-dimensional array is 100, 3 and 97.
  - Repeat this process for each subsequent digit position (tens, hundreds, thousands, etc.).
- On the second (tens digit) pass, 100 is placed in row 0, 3 is placed in row 0 (because 3 has no tens digit) and 97 is placed in row 9. After the gathering pass, the order of the

values in the one-dimensional array is 100, 3 and 97. On the third (hundreds digit) pass, 100 is placed in row 1, 3 is placed in row 0 and 97 is placed in row 0 (after the 3). After this last gathering pass, the original array is in sorted order.

Note that the two-dimensional array of buckets is 10 times the length of the integer array being sorted. This sorting technique provides better performance than a bubble sort, but requires much more memorythe bubble sort requires space for only one additional element of data. This comparison is an example of the spacetime trade-off: The bucket sort uses more memory than the bubble sort, but performs better. This version of the bucket sort requires copying all the data back to the original array on each pass. Another possibility is to create a second two-dimensional bucket array and repeatedly swap the data between the two bucket arrays.

- 16.8 (*Recursive Linear Search*) Modify [Fig. 16.2](#) to use recursive method `recursiveLinearSearch` to perform a linear search of the array. The method should receive the search key and starting index as arguments. If the search key is found, return its index in the array; otherwise, return 1. Each call to the recursive method should check one index in the array.

---

[Page 816]

- 16.9 (*Recursive Binary Search*) Modify [Fig. 16.4](#) to use recursive method `recursiveBinarySearch` to perform a binary search of the array. The method should receive the search key, starting index and ending index as arguments. If the search key is found, return its index in the array. If the search key is not found, return 1.
- 16.10 (*Quicksort*) The recursive sorting technique called quicksort uses the following basic algorithm for a one-dimensional array of values:
- Partitioning Step:* Take the first element of the unsorted array and determine its final location in the sorted array (i.e., all values to the left of the element in the array are less than the element, and all values to the right of the element in the array are greater than the elementwe show how to do this below). We now have one element in its proper location and two unsorted subarrays.
  - Recursive Step:* Perform *Step 1* on each unsorted subarray. Each time *Step 1* is performed on a subarray, another element is placed in its final location of the sorted array, and two unsorted subarrays are created. When a subarray consists of one element, that element is in its final location (because a one-element array is already sorted).

The basic algorithm seems simple enough, but how do we determine the final position of the first element of each subarray? As an example, consider the following set of values (the element in bold is the partitioning elementit will be placed in its final location in the sorted array):

*3* 7 2 6 4 89 8 10 12 68 45

Starting from the right-most element of the array, compare each element with 37 until an element less than 37 is found; then swap 37 and that element. The first element less than 37 is 12, so 37 and 12 are swapped. The new array is

12 2 6 4 89 8 10 *37* 68 45

Element 12 is in italics to indicate that it was just swapped with 37.

Starting from the left of the array, but beginning with the element after 12, compare each element with 37 until an element greater than 37 is foundthen swap 37 and that element. The first element greater than 37 is 89, so 37 and 89 are swapped. The new array is

12 2 6 4 37 8 10 89 68 45

Starting from the right, but beginning with the element before 89, compare each element with 37 until an element less than 37 is found then swap 37 and that element. The first element less than 37 is 10, so 37 and 10 are swapped. The new array is

12 2 6 4 10 8 37 89 68 45

Starting from the left, but beginning with the element after 10, compare each element with 37 until an element greater than 37 is found then swap 37 and that element. There are no more elements greater than 37, so when we compare 37 with itself, we know that 37 has been placed in its final location of the sorted array. Every value to the left of 37 is smaller than it, and every value to the right of 37 is larger than it.

Once the partition has been applied on the previous array, there are two unsorted subarrays. The subarray with values less than 37 contains 12, 2, 6, 4, 10 and 8. The subarray with values greater than 37 contains 89, 68 and 45. The sort continues recursively with both subarrays being partitioned in the same manner as the original array.

Based on the preceding discussion, write recursive method `quickSortHelper` to sort a one-dimensional integer array. The method should receive as arguments a starting index and an ending index on the original array being sorted.

## OBJECTIVES

In this chapter you will learn:

- To form linked data structures using references, self-referential classes and recursion.
- The type-wrapper classes that enable programs to process primitive data values as objects.
- To use autoboxing to convert a primitive value to an object of the corresponding type-wrapper class.
- To use auto-unboxing to convert an object of a type-wrapper class to a primitive value.
- To create and manipulate dynamic data structures, such as linked lists, queues, stacks and binary trees.
- Various important applications of linked data structures.
- How to create reusable data structures with classes, inheritance and composition.

## 17.1. Introduction

In previous chapters, we have studied fixed-size [data structures](#) such as one-dimensional and multidimensional arrays. This chapter introduces [dynamic data structures](#) that grow and shrink at execution time. [Linked lists](#) are collections of data items "linked up in a chain" insertions and deletions can be made anywhere in a linked list. [Stacks](#) are important in compilers and operating systems; insertions and deletions are made only at one end of a stack its [top](#). [Queues](#) represent waiting lines; insertions are made at the back (also referred to as the [tail](#)) of a queue and deletions are made from the front (also referred to as the [head](#)). [Binary trees](#) facilitate high-speed searching and sorting of data, eliminating duplicate data items efficiently, representing file-system directories, compiling expressions into machine language and many other interesting applications.

We will discuss each of these major types of data structures and implement programs that create and manipulate them. We use classes, inheritance and composition to create and package these data structures for reusability and maintainability. In [Chapter 19](#), Collections, we discuss Java's predefined classes that implement the data structures discussed in this chapter.

The examples presented here are practical programs that can be used in advanced courses and in industrial applications. The exercises include a rich collection of useful applications.

This chapter's examples manipulate primitive values for simplicity. However, most of the data-structure implementations in this chapter store only [Objects](#). J2SE 5.0 has added a new feature, called boxing, that allows primitive values to be converted to and from objects for use in cases like this. The objects that represent primitive values are instances of Java's so-called type-wrapper classes in package [java.lang](#). We discuss these classes and boxing in the next two sections, so we can use them in this chapter's examples.

We encourage you to attempt the major project described in the special section entitled *Building Your Own Compiler*. You have been using a Java compiler to translate your Java programs to bytecodes so that you could execute these programs on your computer. In this project, you will actually build your own compiler. It will read a file of statements written in a simple, yet powerful high-level language similar to early versions of the popular language BASIC. Your compiler will translate these statements into a file of Simpletron Machine Language (SML) instructions SML is the language you learned in the [Chapter 7](#) special section, *Building Your Own Computer*. Your Simpletron Simulator program will then execute the SML program produced by your compiler! Implementing this project by using an object-oriented approach will give you a wonderful opportunity to exercise most of what you have learned in this book. The special section carefully walks you through the specifications of the high-level language and describes the algorithms you will need to convert each high-level language statement into machine-language instructions. If you enjoy being challenged, you might attempt the many enhancements to both the compiler and the Simpletron Simulator suggested in the exercises.

## 17.2. Type-Wrapper Classes for Primitive Types

Each primitive type (listed in [Appendix D](#), Primitive Types) has a corresponding [type-wrapper class](#) (in package `java.lang`). These classes are called `Boolean`, `Byte`, `Character`, `Double`, `Float`, `Integer`, `Long` and `Short`. Each type-wrapper class enables you to manipulate primitive-type values as objects. Many of the data structures that we develop or reuse in [Chapters 1719](#) manipulate and share `Objects`. These classes cannot manipulate variables of primitive types, but they can manipulate objects of the type-wrapper classes, because every class ultimately derives from `Object`.

Each of the numeric type-wrapper classes `Byte`, `Short`, `Integer`, `Long`, `Float` and `Double` extends class `Number`. Also, the type-wrapper classes are `final` classes, so you cannot extend them.

Primitive types do not have methods, so the methods related to a primitive type are located in the corresponding type-wrapper class (e.g., method `parseInt`, which converts a `String` to an `int` value, is located in class `Integer`). If you need to manipulate a primitive value in your program, first refer to the documentation for the type-wrapper class—the method you need might already be declared.

## 17.3. Autoboxing and Auto-Unboxing

In versions of Java prior to J2SE 5.0, if you wanted to insert a primitive value into a data structure that could store only **Objects**, you had to create a new object of the corresponding type-wrapper class, then insert this object in the collection. Similarly, if you wanted to retrieve an object of a type-wrapper class from a collection and manipulate its primitive value, you had to invoke a method on the object to obtain its corresponding primitive-type value. For example, suppose you want to add an **int** to an array that stores only references to **Integer** objects. Prior to J2SE 5.0, you would be required to "wrap" an **int** value in an **Integer** object before adding the integer to the array and to "unwrap" the **int** value from the **Integer** object to retrieve the value from the array, as in

```
Integer[] integerArray = new Integer[5]; // create integerArray

// assign Integer 10 to integerArray[0]
integerArray[0] = new Integer(10);

// get int value of Integer
int value = integerArray[0].intValue();
```

Notice that the **int** primitive value **10** is used to initialize an **Integer** object. This achieves the desired result but requires extra code and is cumbersome. We then need to invoke method **intValue** of class **Integer** to obtain the **int** value in the **Integer** object.

J2SE 5.0 simplifies converting between primitive-type values and type-wrapper objects, requiring no additional code on the part of the programmer. J2SE 5.0 introduces two new conversions: the boxing conversion and the unboxing conversion. A **boxing conversion** converts a value of a primitive type to an object of the corresponding type-wrapper class. An **unboxing conversion** converts an object of a type-wrapper class to a value of the corresponding primitive type. J2SE 5.0 allows these conversions to be performed automatically (called **autoboxing** and **auto-unboxing**). For example, the previous statements can be rewritten as

```
Integer[] integerArray = new Integer[5]; // create integerArray
integerArray[0] = 10; // assign Integer 10 to integerArray[0]
int value = integerArray[0]; // get int value of Integer
```

In this case, autoboxing occurs when assigning an **int** value (**10**) to **integerArray[ 0 ]**, because **integerArray** stores references to **Integer** objects, not **int** primitive values. Auto-unboxing occurs when assigning **integerArray[ 0 ]** to **int** variable **value**, because variable **value** stores an **int** value, not a reference to an **Integer** object. Autoboxing and auto-unboxing also occur in control statements: the condition of a control statement can evaluate to a primitive **boolean** type or a **Boolean** reference type. Many of this chapter's examples use these conversions to store primitive values in and retrieve them from data structures that store only references to **Objects**.

## 17.4. Self-Referential Classes

A **self-referential class** contains an instance variable that refers to another object of the same class type. For example, the declaration

```
class Node
{
 private int data;
 private Node nextNode; // reference to next linked node

 public Node(int data) { /* constructor body */ }
 public void setData(int data) { /* method body */ }
 public int getData() { /* method body */ }
 public void setNext(Node next) { /* method body */ }
 public Node getNext() { /* method body */ }
} // end class Node
```

declares class **Node**, which has two **private** instance variables: integer **data** and **Node** reference **nextNode**. Field **nextNode** references a **Node** object, an object of the same class being declared here; hence, the term "self-referential class." Field **nextNode** is a **link** it "links" an object of type **Node** to another object of the same type. Type **Node** also has five methods: a constructor that receives an **Integer** to initialize **data**, a **setData** method to set the value of **data**, a **getData** method to return the value of **data**, a **setNext** method to set the value of **nextNode** and a **getNext** method to return a reference to the next node.

Programs can link self-referential objects together to form such useful data structures as lists, queues, stacks and trees. [Figure 17.1](#) illustrates two self-referential objects linked together to form a list. A **null** reference is placed in the link member of the second self-referential object to indicate that the link does not refer to another object. Note the **null** is illustrative; it does not correspond to the **null** character in Java. Normally, a **null** reference indicates the end of a data structure. There are other ways to represent the end of a data structure that are beyond the scope of this text.

Figure 17.1. Self-referential-class objects linked together.

[\[View full size image\]](#)

## 17.5. Dynamic Memory Allocation

Creating and maintaining dynamic data structures requires [dynamic memory allocation](#) the ability for a program to obtain more memory space at execution time to hold new nodes and to release space no longer needed. Remember that Java programs do not explicitly release dynamically allocated memory. Rather, Java performs automatic garbage collection of objects that are no longer referenced in a program.

The limit for dynamic memory allocation can be as large as the amount of available physical memory in the computer or the amount of available disk space in a virtual-memory system. Often, the limits are much smaller, because the computer's available memory must be shared among many applications.

The declaration and class-instance creation expression

```
Node nodeToAdd = new Node(10); // 10 is nodeToAdd's data
```

allocates the memory to store a `Node` object and returns a reference to the object, which is assigned to `nodeToAdd`. If insufficient memory is available, the expression throws an `OutOfMemoryError`.

The following sections discuss lists, stacks, queues and trees that all use dynamic memory allocation and self-referential classes to create dynamic data structures.

## 17.6. Linked Lists

A linked list is a linear collection (i.e., a sequence) of self-referential-class objects, called [nodes](#), connected by reference linkshence, the term "linked" list. Typically, a program accesses a linked list via a reference to the first node in the list. The program accesses each subsequent node via the link reference stored in the previous node. By convention, the link reference in the last node is set to `null` to mark the end of the list. Data is stored in a linked list dynamicallythe program creates each node as necessary. A node can contain data of any type, including references to objects of other classes. Stacks and queues are also linear data structures and, as we will see, are constrained versions of linked lists. Trees are non-linear data structures.

Lists of data can be stored in arrays, but linked lists provide several advantages. A linked list is appropriate when the number of data elements to be represented in the data structure is unpredictable. Linked lists are dynamic, so the length of a list can increase or decrease as necessary. The size of a "conventional" Java array, however, cannot be altered, because the array size is fixed at the time the program creates the array. "Conventional" arrays can become full. Linked lists become full only when the system has insufficient memory to satisfy dynamic storage allocation requests. Package `java.util` contains class `LinkedList` for implementing and manipulating linked lists that grow and shrink during program execution. We discuss class `LinkedList` in [Chapter 19](#).

### Performance Tip 17.1

*An array can be declared to contain more elements than the number of items expected, but this wastes memory. Linked lists provide better memory utilization in these situations. Linked lists allow the program to adapt to storage needs at runtime.*

### Performance Tip 17.2

*Insertion into a linked list is fastonly two references have to be modified (after locating the insertion point). All existing node objects remain at their current locations in memory.*

Linked lists can be maintained in sorted order simply by inserting each new element at the proper point in the list. (It does, of course, take time to locate the proper insertion point.) Existing list elements do not need to be moved.

### Performance Tip 17.3

*Insertion and deletion in a sorted array can be time consuming all the elements following the inserted or deleted element must be shifted appropriately.*

Linked list nodes normally are not stored contiguously in memory. Rather, they are logically contiguous. [Figure 17.2](#) illustrates a linked list with several nodes. This diagram presents a [singly linked list](#) each node contains one reference to the next node in the list. Often, linked lists are implemented as doubly linked list each node contains a reference to the next node in the list and a reference to the previous node in the list. Java's `LinkedList` class is a doubly linked list implementation.

Figure 17.2. Linked list graphical representation.

[\[View full size image\]](#)

#### Performance Tip 17.4

*Normally, the elements of an array are contiguous in memory. This allows immediate access to any array element, because its address can be calculated directly as its offset from the beginning of the array. Linked lists do not afford such immediate access to their elements an element can be accessed only by traversing the list from the front (or from the back in a doubly linked list).*

The program of [Fig. 17.3](#) [Fig. 17.5](#) uses an object of our `List` class to manipulate a list of miscellaneous objects. The program consists of four classes `ListNode` ([Fig. 17.3](#), lines 637), `List` ([Fig. 17.3](#), lines 40147), `EmptyListException` ([Fig. 17.4](#)) and `ListTest` ([Fig. 17.5](#)). The `List`, `ListNode` and `EmptyListException` classes are placed in package `com.deitel.jhtp6.ch17`, so they can be reused throughout this chapter. Encapsulated in each `List` object is a linked list of `ListNode` objects. [Note: Many of the classes in this chapter are declared in the package `com.deitel.jhtp6.ch17`. Each such class should be compiled with the `-d` command-line option to `javac`. When compiling the classes that are not in this package and when running the programs, be sure to use the `-classpath` option to `javac` and `java`, respectively.]

Figure 17.3. `ListNode` and `List` class declarations.

```

1 // Fig. 17.3: List.java
2 // ListNode and List class definitions.
3 package com.deitel.jhtp6.ch17;
4
5 // class to represent one node in a list
6 class ListNode
7 {
8 // package access members; List can access these directly
9 Object data;
10 ListNode nextNode;
11
12 // constructor creates a ListNode that refers to object
13 ListNode(Object object)
14 {
15 this (object, null);
16 } // end ListNode one-argument constructor
17
18 // constructor creates ListNode that refers to
19 // Object and to next ListNode
20 ListNode(Object object, ListNode node)
21 {
22 data = object;
23 nextNode = node;
24 } // end ListNode two-argument constructor
25
26 // return reference to data in node
27 Object getObject()
28 {
29 return data; // return Object in this node
30 } // end method getObject
31
32 // return reference to next node in list
33 ListNode getNext()
34 {
35 return nextNode; // get next node
36 } // end method getNext
37 } // end class ListNode
38
39 // class List definition
40 public class List
41 {

Class `ListNode` (Fig. 17.3, lines 637) declares package-access fields `data` and `nextNode`. The `data` field is an `Object` reference, so it can refer to any object. `ListNode` member `nextNode` stores a reference to the `next` `ListNode` object in the linked list (or `null` if the node is the last one in the list).

---

[Page 826]

Lines 4243 of class `List` (Fig. 17.3, lines 40147) declare references to the first and last `ListNode`s in a `List` (`firstNode` and `lastNode`, respectively). The constructors (lines 4750 and 5357) initialize both references to `null`. The most important methods of class `List` are `insertAtFront` (lines 6066), `insertAtBack` (lines 6975), `removeFromFront` (lines 7892) and `removeFromBack` (lines 95118). Method `isEmpty` (lines 121124) is a *predicate method* that determines whether the list is empty (i.e., the reference to the first node of the list is `null`). Predicate methods typically test a condition and do not modify the object on which they are called. If the list is empty, method `isEmpty` returns `TRue`; otherwise, it returns `false`. Method `print` (lines 127146) displays the list's contents. A detailed discussion of `List`'s methods follows Fig. 17.5.

Method `main` of class `ListTest` (Fig. 17.5) inserts objects at the beginning of the list using method `insertAtFront`, inserts objects at the end of the list using method `insertAtBack`, deletes objects from the front of the list using method `removeFromFront` and deletes objects from the end of the list using method `removeFromBack`. After each insert and remove operation, `ListTest` calls `List` method `print` to display the current list contents. If an attempt is made to remove an item from an empty list, an `EmptyListException` (Fig. 17.4) is thrown, so the method calls to `removeFromFront` and `removeFromBack` are placed in a `try` block that is followed by an appropriate exception handler. Notice in lines 13, 15, 17 and 19 that the applications passes literal primitive `int` values to methods `insertAtFront` and `insertAtBack`, even though each of these methods was declared with a parameter of type `Object` (Fig. 17.3, lines 60 and 69). In this case, the JVM autoboxes each literal value in an `Integer` object and that object is actually inserted into the list. This, of course, is allowed because `Object` is an indirect superclass of `Integer`.

---

[Page 827]

---

[Page 828]

Now we discuss each method of class `List` (Fig. 17.3) in detail and provide diagrams showing the reference

manipulations performed by methods `insertAtFront`, `insertAtBack`, `removeFromFront` and `removeFromBack`. Method `insertAtFront` (lines 6066 of [Fig. 17.3](#)) places a new node at the front of the list. The steps are:

1. Call `isEmpty` to determine whether the list is empty (line 62).
2. If the list is empty, assign `firstNode` and `lastNode` to the new `ListNode` that was initialized with `insertItem` (line 63). The `ListNode` constructor at lines 1316 calls the `ListNode` constructor at lines 2024 to set instance variable `data` to refer to the `insertItem` passed as an argument and to set reference `nextNode` to `null`, because this is the first and last node in the list.
3. If the list is not empty, the new node is "linked" into the list by setting `firstNode` to a new `ListNode` object and initializing that object with `insertItem` and `firstNode` (line 65). When the `ListNode` constructor (lines 2024) executes, it sets instance variable `data` to refer to the `insertItem` passed as an argument and performs the insertion by setting the `nextNode` reference of the new node to the `ListNode` passed as an argument, which previously was the first node.

In [Fig. 17.6](#), part (a) shows a list and a new node during the `insertAtFront` operation and before the program links the new node into the list. The dotted arrows in part (b) illustrate *Step 3* of the `insertAtFront` operation that enables the node containing 12 to become the new first node in the list.

Figure 17.6. Graphical representation of operation `insertAtFront`.

(This item is displayed on page 829 in the print version)

[\[View full size image\]](#)

Method `insertAtBack` (lines 6975 of [Fig. 17.3](#)) places a new node at the back of the list. The steps are:

1. Call `isEmpty` to determine whether the list is empty (line 71).
2. If the list is empty, assign `firstNode` and `lastNode` to the new `ListNode` that was initialized with `insertItem` (line 72). The `ListNode` constructor at lines 1316 calls the constructor at lines 2024 to set instance variable `data` to refer to the `insertItem` passed as an argument and to set reference `nextNode` to `null`.

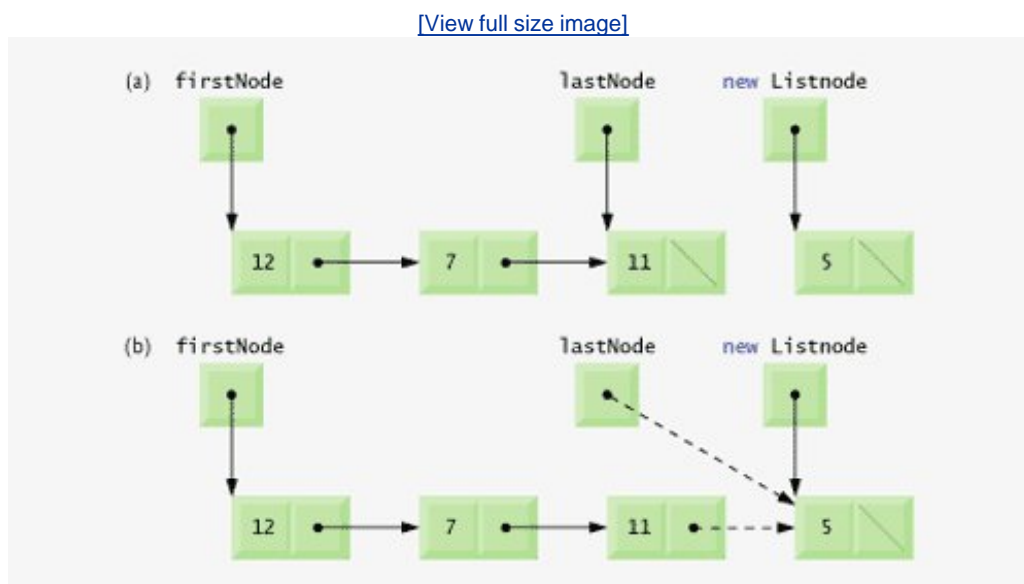

---

[Page 829]

3. If the list is not empty, line 74 links the new node into the list by assigning to `lastNode` and `lastNode.nextNode` the reference to the new `ListNode` that was initialized with `insertItem`. `ListNode`'s constructor (lines 1316), sets instance variable `data` to refer to the `insertItem` passed as an argument and sets reference `nextNode` to `null`, because this is the last node in the list.

In [Fig. 17.7](#), part (a) shows a list and a new node during the `insertAtBack` operation and before the program links the new node into the list. The dotted arrows in part (b) illustrate *Step 3* of method `insertAtBack`, which adds the new node to the end of a list that is not empty.

Figure 17.7. Graphical representation of operation `insertAtBack`.

---

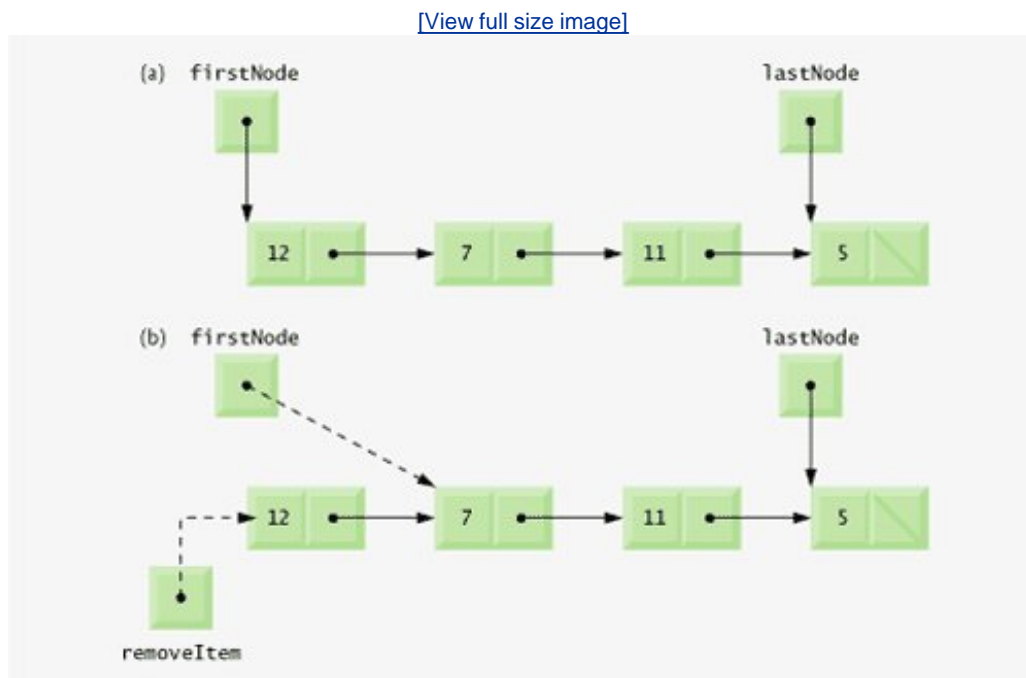

[Page 830]

Method `removeFromFront` (lines 7892 of [Fig. 17.3](#)) removes the first node of the list and returns a reference to the removed data. The method throws an `EmptyListException` (lines 8081) if the list is empty when the program calls this method. Otherwise, the method returns a reference to the removed data. The steps are:

1. Assign `firstNode.data` (the data being removed from the list) to reference `removedItem` (line 83).
2. If `firstNode` and `lastNode` refer to the same object (line 86), the list has only one element at this time. So, the method sets `firstNode` and `lastNode` to `null` (line 87) to remove the node from the list (leaving the list empty).
3. If the list has more than one node, then the method leaves reference `lastNode` as is and assigns the value of `firstNode.nextNode` to `firstNode` (line 89). Thus, `firstNode` references the node that was previously the second node in the list.
4. Return the `removedItem` reference (line 91).

In [Fig. 17.8](#), part (a) illustrates the list before the removal operation. The dashed lines and arrows in part (b) show the reference manipulations.

Figure 17.8. Graphical representation of operation `removeFromFront`.

Method `removeFromBack` (lines 95118 of [Fig. 17.3](#)) removes the last node of a list and returns a reference to the removed data. The method throws an `EmptyListException` (lines 9798) if the list is empty when the program calls this method. The steps are:

1. Assign `lastNode.data` (the data being removed from the list) to `removedItem` (line 100).

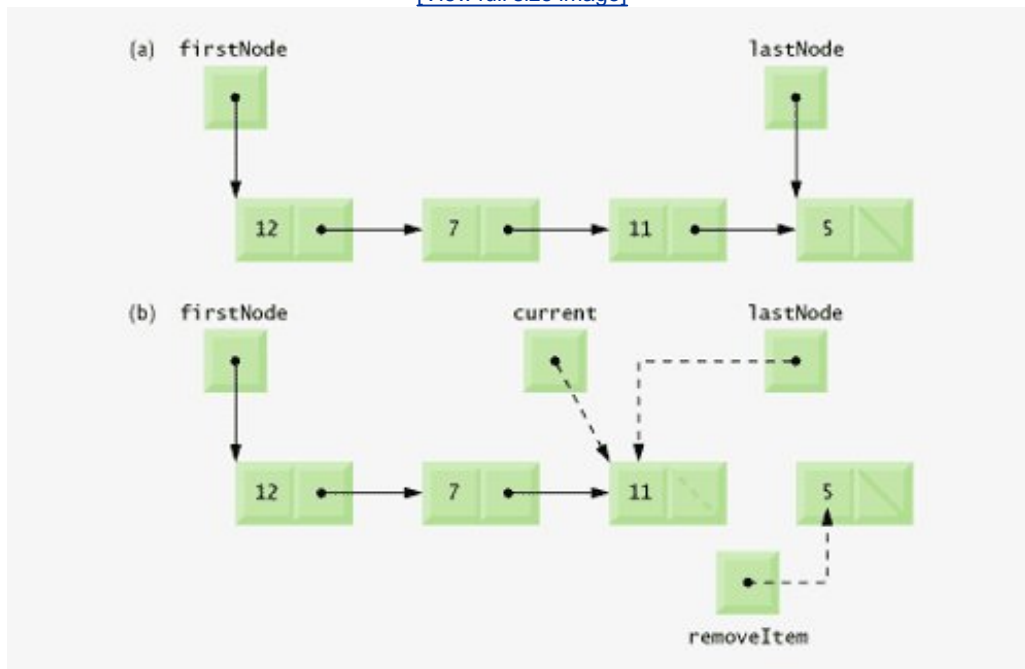

[Page 831]

2. If the `firstNode` and `lastNode` refer to the same object (line 103), the list has only one element at this time. So, line 104 sets `firstNode` and `lastNode` to `null` to remove that node from the list (leaving the list empty).
3. If the list has more than one node, create the `ListNode` reference `current` and assign it `firstNode` (line 107).
4. Now "walk the list" with `current` until it references the node before the last node. The `while` loop (lines 110-111) assigns `current.nextNode` to `current` as long as `current.nextNode` (the next node in the list) is not `lastNode`.
5. After locating the second-to-last node, assign `current` to `lastNode` (line 113) to update which node is last in the list.
6. Set the `current.nextNode` to `null` (line 114) to remove the last node from the list and terminate the list at the `current` node.
7. Return the `removedItem` reference (line 117).

In [Fig. 17.9](#), part (a) illustrates the list before the removal operation. The dashed lines and arrows in part (b) show the reference manipulations.

Figure 17.9. Graphical representation of operation `removeFromBack`.

[\[View full size image\]](#)

Method `print` (lines 127-146) first determines whether the list is empty (lines 129-133). If so, `print` displays a message indicating that the list is empty and returns control to the calling method. Otherwise, `print` outputs the list's data. Line 136 creates `ListNode` `current` and initializes it with `firstNode`. While `current` is

not `null`, there are more items in the list. Therefore, line 141 outputs a string representation of `current.data`. Line 142 moves to the next node in the list by assigning the value of reference `current.nextNode` to `current`. This printing algorithm is identical for linked lists, stacks and queues.

## 17.7. Stacks

A stack is a constrained version of a linked list; new nodes can be added to and removed from a stack only at the top. [Note: A stack does not have to be implemented using a linked list.] For this reason, a stack is referred to as a **last-in, first-out (LIFO)** data structure. The link member in the bottom (i.e., last) node of the stack is set to `null` to indicate the bottom of the stack.

The primary methods for manipulating a stack are `push` and `pop`. Method `push` adds a new node to the top of the stack. Method `pop` removes a node from the top of the stack and returns the data from the popped node.

Stacks have many interesting applications. For example, when a program calls a method, the called method must know how to return to its caller, so the return address of the calling method is pushed onto the **program execution stack**. If a series of method calls occurs, the successive return addresses are pushed onto the stack in last-in, first-out order so that each method can return to its caller. Stacks support recursive method calls in the same manner as they do conventional nonrecursive method calls.

The program execution stack also contains the memory for local variables on each invocation of a method during a program's execution. When the method returns to its caller, the memory for that method's local variables is popped off the stack, and those variables are no longer known to the program. If the local variable is a reference, the reference count for the object to which it referred is decremented by 1. If the reference count becomes zero, the object can be garbage collected.

Compilers use stacks to evaluate arithmetic expressions and generate machine-language code to process the expressions. The exercises in this chapter explore several applications of stacks, including using them to develop a complete working compiler. Also, package `java.util` contains class `Stack` (see [Chapter 19](#)) for implementing and manipulating stacks that can grow and shrink during program execution.

We take advantage of the close relationship between lists and stacks to implement a stack class by reusing a list class. We demonstrate two different forms of reusability. First, we implement the stack class by extending class `List` of [Fig. 17.3](#). Then we implement an identically performing stack class through composition by including a reference to a `List` object as a private instance variable of a stack class. The list, stack and queue data structures in this chapter are implemented to store `Object` references to encourage further reusability. Thus, any object type can be stored in a list, stack or queue.

### Stack Class That Inherits from `List`

The application of [Fig. 17.10](#) and [Fig. 17.11](#) creates a stack class by extending class `List` of [Fig. 17.3](#). We want the stack to have methods `push`, `pop`, `isEmpty` and `print`. Essentially, these are the methods `insertAtFront`, `removeFromFront`, `isEmpty` and `print` of class `List`. Of course, class `List` contains other methods (such as `insertAtBack` and `removeFromBack`) that we would rather not make accessible through the `public` interface to the stack class. It is important to remember that all methods in the `public` interface of class `List` class also are `public` methods of the subclass `StackInheritance` ([Fig. 17.10](#)). When we implement the stack's methods, we have each `StackInheritance` method call the appropriate `List` method: method `push` calls `insertAtFront` and method `pop` calls `removeFromFront`. Clients of class `StackInheritance` can call methods `isEmpty` and `print` because they are inherited from `List`. Class `StackInheritance` is declared as part of package `com.deitel.jhtp6.ch17` for reuse purposes. Note that `StackInheritance` does not import `List`, because both classes are in the same package.

Figure 17.10. `StackInheritance` extends class `List`.

```

1 // Fig. 17.10: StackInheritance.java
2 // Derived from class List.
3 package com.deitel.jhtp6.ch17;
4
5 public class StackInheritance extends List
6 {
7 // no-argument constructor
8 public StackInheritance()
9 {
10 super ("stack");
11 } // end StackInheritance no-argument constructor
12
13 // add object to stack
14 public void push(Object object)
15 {
16 insertAtFront(object);
17 } // end method push
18
19 // remove object from stack
20 public Object pop() throws EmptyListException
21 {
22 return removeFromFront();
23 } // end method pop
24 } // end class StackInheritance

```

```

Class `StackInheritanceTest`'s method `main` ([Fig. 17.11](#)) creates an object of class `StackInheritance` called `stack` (line 10). The program pushes integers onto the stack (lines 13, 15, 17 and 19). Once again, note that autoboxing is used here to insert `Integer` objects into the data structure. Lines 27-32 `pop` the objects from the stack in an infinite `while` loop. If method `pop` is invoked on an empty stack, the method throws an `EmptyListException`. In this case, the program displays the exception's stack trace, which shows the methods on the program execution stack at the time the exception occurred. Note that the program uses method `print` (inherited from `List`) to output the contents of the stack.

## Stack Class That Contains a Reference to a `List`

You can also implement a class by reusing a list class through composition. [Figure 17.12](#) uses a `private List` (line 7) in class `StackComposition`'s declaration. Composition enables us to hide the `List` methods that should not be in our stack's `public` interface. We provide `public` interface methods that use only the required `List` methods. Implementing each stack method as a call to a `List` method is called **delegation**the stack method invoked **delegates** the call to the appropriate `List` method. In particular, `StackComposition` delegates calls to `List` methods `insertAtFront`, `removeFromFront`, `isEmpty` and `print`. In this example, we do not show class `StackCompositionTest`, because the only difference is that we change the type of the stack from `StackInheritance` to `StackComposition` (lines 3 and 10 of [Fig. 17.11](#)). The output is identical using either version of the stack.

Figure 17.12. `StackComposition` uses a composed `List` object.

```
1 // Fig. 17.12: StackComposition.java
2 // Class StackComposition definition with composed List object.
3 package com.deitel.jhttp6.ch17;
4
5 public class StackComposition
6 {
7 private List stackList;
8
9 // no-argument constructor
10 public StackComposition()
11 {
12 stackList = new List("stack");
13 } // end StackComposition no-argument constructor
14
15 // add object to stack
16 public void push(Object object)
17 {
18 stackList.insertAtFront(object);
19 } // end method push
20
21 // remove object from stack
22 public Object pop() throws EmptyListException
23 {
24 return stackList.removeFromFront();
25 } // end method pop
26
27 // determine if stack is empty
28 public boolean isEmpty()
29 {
30 return stackList.isEmpty();
31 } // end method isEmpty
32
33 // output stack contents
34 public void print()
35 {
36 stackList.print();
37 } // end method print
38 } // end class StackComposition
```

## 17.8. Queues

Another commonly used data structure is the queue. A queue is similar to a checkout line in a supermarket: the cashier services the person at the beginning of the line first. Other customers enter the line only at the end and wait for service. Queue nodes are removed only from the head (or front) of the queue and are inserted only at the tail (or end). For this reason, a queue is a **first-in, first-out (FIFO)** data structure. The insert and remove operations are known as **enqueue** and **dequeue**.

Queues have many uses in computer systems. Most computers have only a single processor, so only one application at a time can be serviced. Each application requiring processor time is placed in a queue. The application at the front of the queue is the next to receive service. Each application gradually advances to the front as the applications before it receive service.

Queues are also used to support **print spooling**. For example, a single printer might be shared by all users of a network. Many users can send print jobs to the printer, even when the printer is already busy. These print jobs are placed in a queue until the printer becomes available. A program called a **spooler** manages the queue to ensure that, as each print job completes, the next print job is sent to the printer.

Information packets also wait in queues in computer networks. Each time a packet arrives at a network node, it must be routed to the next node along the path to the packet's final destination. The routing node routes one packet at a time, so additional packets are enqueued until the router can route them.

A file server in a computer network handles file-access requests from many clients throughout the network. Servers have a limited capacity to service requests from clients. When that capacity is exceeded, client requests wait in queues.

[Figure 17.13](#) creates a queue class that contains an object of class **List** ([Fig. 17.3](#)). Class **Queue** ([Fig. 17.13](#)) provides methods **enqueue**, **dequeue**, **isEmpty** and **print**. Class **List** contains other methods (e.g., **insertAtFront** and **removeFromBack**) that we would rather not make accessible through the public interface of class **Queue**. By using composition, these methods in the public interface of class **List** are not accessible to clients of class **Queue**. Each method of class **Queue** calls an appropriate **List** method: method **enqueue** calls **List** method **insertAtBack**, method **dequeue** calls **List** method **removeFromFront**, method **isEmpty** calls **List** method **isEmpty** and method **print** calls **List** method **print**. For reuse purposes, class **Queue** is declared in package **com.deitel.jhtp6.ch17**.

Figure 17.13. **Queue** uses class **List**.

(This item is displayed on pages 836 - 837 in the print version)

```

1 // Fig. 17.13: Queue.java
2 // Class Queue.
3 package com.deitel.jhtp6.ch17;
4
5 public class Queue
6 {
7 private List queueList;
8
9 // no-argument constructor
10 public Queue()
11 {
12 queueList = new List("queue");
13 } // end Queue no-argument constructor
14
15 // add object to queue
16 public void enqueue(Object object)
17 {
18 queueList.insertAtBack(object);
19 } // end method enqueue
20
21 // remove object from queue
22 public Object dequeue() throws EmptyListException
23 {
24 return queueList.removeFromFront();
25 } // end method dequeue
26
27 // determine if queue is empty
28 public boolean isEmpty()
29 {
30 return queueList.isEmpty();
31 } // end method isEmpty
32
33 // output queue contents
34 public void print()
35 {
36 queueList.print();
37 } // end method print
38 } // end class Queue

```

Class `QueueTest` (Fig. 17.14) method `main` creates an object of class `Queue` called `queue`. Lines 13, 15, 17 and 19 enqueue four integers, taking advantage of autoboxing to insert `Integer` objects into the queue. Lines 27-32 use an infinite `while` loop to dequeue the objects in first-in, first-out order. When the queue is empty, method `dequeue` throws an `EmptyListException`, and the program displays the exception's stack trace.

## 17.9. Trees

Linked lists, stacks and queues are [linear data structures](#) (i.e., [sequences](#)). A tree is a nonlinear, two-dimensional data structure with special properties. Tree nodes contain two or more links. This section discusses binary trees ([Fig. 17.15](#)) trees whose nodes each contain two links (one or both of which may be [null](#)). The [root node](#) is the first node in a tree. Each link in the root node refers to a [child](#). The [left child](#) is the first node in the [left subtree](#) (also known as the root node of the left subtree), and the [right child](#) is the first node in the [right subtree](#) (also known as the root node of the right subtree). The children of a specific node are called [siblings](#). A node with no children is called a [leaf node](#). Computer scientists normally draw trees from the root node down exactly the opposite of the way most trees grow in nature.

Figure 17.15. Binary tree graphical representation.

[\[View full size image\]](#)

In our example, we create a special binary tree called a [binary search tree](#). A binary search tree (with no duplicate node values) has the characteristic that the values in any left subtree are less than the value in that subtree's parent node, and the values in any right subtree are greater than the value in that subtree's parent node. [Figure 17.16](#) illustrates a binary search tree with 12 integer values. Note that the shape of the binary search tree that corresponds to a set of data can vary, depending on the order in which the values are inserted into the tree.

Figure 17.16. Binary search tree containing 12 values.

[\[View full size image\]](#)

The application of [Fig. 17.17](#) and [Fig. 17.18](#) creates a binary search tree of integers and traverses it (i.e., walks through all its nodes) three ways using recursive [inorder](#), [preorder](#) and [postorder traversals](#). The program generates 10 random numbers and inserts each into the tree. Class `tree` is declared in package `com.deitel.jhtp6.ch17` for reuse purposes.

Figure 17.17. `TreeNode` and `tree` class declarations for a binary search tree.

(This item is displayed on pages 840 - 842 in the print version)

---

[Page 842]

Let us walk through the binary tree program. Method `main` of class `TReeTest` ([Fig. 17.18](#)) begins by instantiating an empty `TRee` object and assigning its reference to variable `tree` (line 10). Lines 1722 randomly generate 10 integers, each of which is inserted into the binary tree through a call to method `insertNode` (line 21). The program then performs preorder, inorder and postorder traversals (these will be explained shortly) of `tree` (lines 25, 28 and 31, respectively).

Class `tree` ([Fig. 17.17](#), lines 44113) has `private` field `root` (line 46) a `TTreeNode` reference to the root node of the tree. `tree`'s constructor (lines 4952) initializes `root` to `null` to indicate that the tree is empty. The class contains method `insertNode` (lines 5561) to insert a new node in the tree and methods `preorderTraversal` (lines 6467), `inorderTraversal` (lines 8184) and `postorderTraversal` (lines 98101) to begin traversals of the tree. Each of these methods calls a recursive utility method to perform the traversal operations on the internal representation of the tree. (Recursion is discussed in [Chapter 15](#).)

Class `TRee`'s method `insertNode` (lines 5561) first determines whether the tree is empty. If so, line 58 allocates a new `TTreeNode`, initializes the node with the integer being inserted in the tree and assigns the new node to reference `root`. If the tree is not empty, line 60 calls `TTreeNode` method `insert` (lines 2141). This method uses recursion to determine the location for the new node in the tree and inserts the node at that location. A node can be inserted only as a leaf node in a binary search tree.

`TTreeNode` method `insert` compares the value to insert with the `data` value in the root node. If the insert value is less than the root node data (line 24), the program determines if the left subtree is empty (line 27). If so, line 28 allocates a new `treeNode`, initializes it with the integer being inserted and assigns the new node to reference `leftNode`. Otherwise, line 30 recursively calls `insert` for the left subtree to insert the value into the left subtree. If the insert value is greater than the root node data (line 32), the program determines if the right subtree is empty (line 35). If so, line 36 allocates a new `treeNode`, initializes it with the integer being inserted and assigns the new node to reference `rightNode`. Otherwise, line 38 recursively calls `insert` for the right subtree to insert the value in the right subtree. If the `insertValue` is already in the tree, it is simply ignored.

Methods `inorderTraversal`, `preorderTraversal` and `postorderTraversal` call `tree` helper methods `inorderHelper` (lines 8795), `preorderHelper` (lines 7078) and `postorderHelper` (lines 104112), respectively, to traverse the tree and print the node values. The helper methods in class `tree` enable the programmer to start a traversal without having to pass the `root` node to the method. Reference `root` is an implementation detail that a programmer should not be able to access. Methods `inorderTraversal`, `preorderTraversal` and `postorderTraversal` simply take the private `root` reference and pass it to the appropriate helper method to initiate a traversal of the tree. The base case for each helper method determines whether the reference it receives is `null` and, if so, returns immediately.

---

[Page 843]

---

Method `inorderHelper` (lines 8795) defines the steps for an inorder traversal:

1. Traverse the left subtree with a call to `inorderHelper` (line 92).
2. Process the value in the node (line 93).
3. Traverse the right subtree with a call to `inorderHelper` (line 94).

The inorder traversal does not process the value in a node until the values in that node's left subtree are processed. The inorder traversal of the tree in [Fig. 17.19](#) is

6 13 17 27 33 42 48

Figure 17.19. Binary search tree with seven values.

[\[View full size image\]](#)

Note that the inorder traversal of a binary search tree prints the node values in ascending order. The process of creating a binary search tree actually sorts the data; thus, it is called the [binary tree sort](#).

Method `preorderHelper` (lines 7078) defines the steps for a preorder traversal:

1. Process the value in the node (line 75)
2. Traverse the left subtree with a call to `preorderHelper` (line 76).
3. Traverse the right subtree with a call to `preorderHelper` (line 77).

The preorder traversal processes the value in each node as the node is visited. After processing the value in a given node, the preorder traversal processes the values in the left subtree, then the values in the right subtree. The preorder traversal of the tree in [Fig. 17.19](#) is

27 13 6 17 42 33 48

Method `postorderHelper` (lines 104112) defines the steps for a postorder traversal:

1. Traverse the left subtree with a call to `postorderHelper` (line 109).
2. Traverse the right subtree with a call to `postorderHelper` (line 110).
3. Process the value in the node (line 111).

The postorder traversal processes the value in each node after the values of all that node's children are processed. The `postorderTraversal` of the tree in [Fig. 17.19](#) is

6 17 13 33 48 42 27

---

[Page 845]

The binary search tree facilitates [duplicate elimination](#). While building a tree, the insertion operation recognizes attempts to insert a duplicate value, because a duplicate follows the same "go left" or "go right" decisions on each comparison as the original value did. Thus, the insertion operation eventually compares the duplicate with a node containing the same value. At this point, the insertion operation can decide to discard the duplicate value (as we do in this example).

Searching a binary tree for a value that matches a key value is fast, especially for [tightly packed \(or balanced\) trees](#). In a tightly packed tree, each level contains about twice as many elements as the previous level. [Figure 17.19](#) is a tightly packed binary tree. A tightly packed binary search tree with  $n$  elements has  $\log_2 n$  levels. Thus, at most  $\log_2 n$  comparisons are required either to find a match or to determine that no match exists. Searching a (tightly packed) 1000-element binary search tree requires at most 10 comparisons, because  $2^{10} > 1000$ . Searching a (tightly packed) 1,000,000-element binary search tree requires at most 20 comparisons, because  $2^{20} > 1,000,000$ .

The chapter exercises present algorithms for several other binary tree operations, such as deleting an item from a binary tree, printing a binary tree in a two-dimensional tree format and performing a [level-order traversal of a binary tree](#). The level-order traversal visits the nodes of the tree row by row, starting at the root node level. On each level of the tree, a level-order traversal visits the nodes from left to right.

## 17.10. Wrap-Up

In this chapter, you learned about type-wrapper classes, boxing and dynamic data structures that grow and shrink at execution time. You learned that each primitive type has a corresponding type-wrapper class in package `java.lang`. You also saw that Java can convert between primitive values and objects of the type-wrapper classes using J2SE 5.0's new feature called boxing.

You learned that linked lists are collections of data items that are "linked up in a chain." You also saw that an application can perform insertions and deletions anywhere in a linked list. You learned that the stack and queue data structures are constrained versions of lists. For stacks, you saw that insertions and deletions are made only at its top. For queues that represent waiting lines, you saw that insertions are made at the tail and deletions are made from the head. You also learned the binary tree data structure. You saw a binary search tree that facilitated high-speed searching and sorting of data and eliminating duplicate data items efficiently. Throughout the chapter, you learned how to create and package these data structures for reusability and maintainability.

In [Chapter 18](#), Generics, we discuss J2SE 5.0's new feature called generics, which provides a mechanism for declaring classes and methods without specific type information so that the classes and methods can be used with many different reference types. Generics are used extensively in Java's built-in set of data structures, known as the Collections API. You will learn about collections in [Chapter 19](#), Collections.

## Summary

- Dynamic data structures can grow and shrink at execution time.
- Linked lists are collections of data items "linked up in a chain" insertions and deletions can be made anywhere in a linked list.
- Stacks are important in compilers and operating systems insertions and deletions are made only at one end of a stack, its top.
- Queues represent waiting lines; insertions are made at the tail of a queue and deletions are made from the head.
- Binary trees facilitate high-speed searching and sorting of data, eliminating duplicate data items efficiently, representing file-system directories and compiling expressions into machine language.
- Type-wrapper classes (e.g., `Integer`, `Double`, `Boolean`) enable programmers to manipulate primitive-type values as objects. Objects of these classes can be used in collections and data structures that can store only references to objects not primitive-type values.
- J2SE 5.0 introduces two new conversions, the boxing conversion and the unboxing conversion. A boxing conversion converts a value of a primitive type to an object of the corresponding type-wrapper class. An unboxing conversion converts an object of a type-wrapper class to a value of the corresponding primitive type.
- J2SE 5.0 performs boxing conversions and unboxing conversions automatically (called autoboxing and auto-unboxing).
- A self-referential class contains a reference that refers to another object of the same class type. Self-referential objects can be linked together to form dynamic data structures.
- The limit for dynamic memory allocation can be as large as the available physical memory in the computer or the amount of available disk space in a virtual-memory system. Often, the limits are much smaller because the computer's available memory must be shared among many users.
- If no memory is available, an `OutOfMemoryError` is thrown.
- A linked list is accessed via a reference to the first node of the list. Each subsequent node is accessed via the link-reference member stored in the previous node.
- By convention, the link reference in the last node of a list is set to `null` to mark the end of the list.
- A node can contain data of any type, including objects of other classes.
- A linked list is appropriate when the number of data elements to be stored is unpredictable. Linked lists are dynamic, so the length of a list can increase or decrease as necessary.
- The size of a "conventional" Java array cannot be altered it is fixed at creation time.
- Linked lists can be maintained in sorted order simply by inserting each new element at the proper point in the list.
- List nodes normally are not stored contiguously in memory. Rather, they are logically contiguous.
- A stack is a last-in, first-out (LIFO) data structure. The primary methods used to manipulate a stack are `push` and `pop`. Method `push` adds a new node to the top of the stack. Method `pop` removes a node

from the top of the stack and returns the `data` object from the popped node.

- Stacks have many interesting applications. When a method call is made, the called method must know how to return to its caller, so the return address is pushed onto the program execution stack. If a series of method calls occurs, the successive return values are pushed onto the stack in last-in, first-out order so that each method can return to its caller. The program execution stack contains the space created for local variables on each invocation of a method. When the method returns to its caller, the space for that method's local variables is popped off the stack, and those variables are no longer available to the program.

---

[Page 847]

- Stacks are used by compilers to evaluate arithmetic expressions and generate machine-language code to process the expressions.
- The technique of implementing each stack method as a call to a `List` method is called delegation; the stack method invoked delegates the call to the appropriate `List` method.
- A queue is similar to a checkout line in a supermarket: the first person in line is serviced first, and other customers enter the line only at the end and wait to be serviced.
- Queue nodes are removed only from the head of the queue and are inserted only at the tail. For this reason, a queue is referred to as a first-in, first-out (FIFO) data structure.
- The insert and remove operations for a queue are known as `enqueue` and `dequeue`.
- Queues have many uses in computer systems. Most computers have only a single processor, so only one application at a time can be serviced. Entries for the other applications are placed in a queue. The entry at the front of the queue is the next to receive service. Each entry gradually advances to the front of the queue as applications receive service.
- A tree is a nonlinear, two-dimensional data structure. Tree nodes contain two or more links.
- A binary tree is a tree whose nodes all contain two links. The root node is the first node in a tree.
- Each link in the root node refers to a child. The left child is the first node in the left subtree, and the right child is the first node in the right subtree.
- The children of a node are called siblings. A node with no children is called a leaf node.
- A binary search tree (with no duplicate node values) has the characteristic that the values in any left subtree are less than the value in the subtree's parent node, and the values in any right subtree are greater than the value in the subtree's parent node. A node can be inserted only as a leaf node in a binary search tree.
- An inorder traversal of a binary search tree processes the node values in ascending order.
- In a preorder traversal, the value in each node is processed as the node is visited. Then the values in the left subtree are processed, and then the values in the right subtree.
- In a postorder traversal, the value in each node is processed after the values of its children.
- The binary search tree facilitates duplicate elimination. As the tree is created, attempts to insert a duplicate value are recognized, because a duplicate follows the same "go left" or "go right" decisions on each comparison as the original value did. Thus, the duplicate eventually is compared with a node containing the same value. The duplicate value can be discarded at this point.
- Searching a binary tree for a value that matches a key value is also fast, especially for tightly packed trees. In a tightly packed tree, each level contains about twice as many elements as the previous one. So a tightly packed binary search tree with  $n$  elements has  $\log_2 n$  levels, and thus at most  $\log_2 n$  comparisons would have to be made either to find a match or to determine that no match exists. Searching a (tightly packed) 1000-element binary search tree requires at most 10 comparisons, because  $2^{10} > 1000$ . Searching a (tightly packed) 1,000,000-element binary search tree requires at

most 20 comparisons, because  $2^{20} > 1,000,000$ .

## Self-Review Exercises

17.1 Fill in the blanks in each of the following statements:

- a. A self- \_\_\_\_\_ class is used to form dynamic data structures that can grow and shrink at execution time.
- b. A(n) \_\_\_\_\_ is a constrained version of a linked list in which nodes can be inserted and deleted only from the start of the list.
- c. A method that does not alter a linked list, but simply looks at it to determine whether it is empty, is referred to as a(n) \_\_\_\_\_ method.
- d. A queue is referred to as a(n) \_\_\_\_\_ data structure because the first nodes inserted are the first ones removed.
- e. The reference to the next node in a linked list is referred to as a(n) \_\_\_\_\_.
- f. Automatically reclaiming dynamically allocated memory in Java is called \_\_\_\_\_.
- g. A(n) \_\_\_\_\_ is a constrained version of a linked list in which nodes can be inserted only at the end of the list and deleted only from the start of the list.
- h. A(n) \_\_\_\_\_ is a nonlinear, two-dimensional data structure that contains nodes with two or more links.
- i. A stack is referred to as a(n) \_\_\_\_\_ data structure because the last node inserted is the first node removed.
- j. The nodes of a(n) \_\_\_\_\_ tree contain two link members.
- k. The first node of a tree is the \_\_\_\_\_ node.
- l. Each link in a tree node refers to a(n) \_\_\_\_\_ or \_\_\_\_\_ of that node.
- m. A tree node that has no children is called a(n) \_\_\_\_\_ node.
- n. The three traversal algorithms we mentioned in the text for binary search trees are \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.

---

[Page 849]

- o. Assuming that `myArray` contains references to `Double` objects, \_\_\_\_\_ occurs when the statement `"double number = myArray[ 0 ];"` executes.
- p. Assuming that `myArray` contains references to `Double` objects, \_\_\_\_\_ occurs when the statement `"myArray[ 0 ] = 1.25;"` executes.

17.2 What are the differences between a linked list and a stack?

17.3 What are the differences between a stack and a queue?

17.4 Perhaps a more appropriate title for this chapter would have been "Reusable Data Structures." Comment on how each of the following entities or concepts contributes to the reusability of data

structures:

- a. classes
- b. inheritance
- c. composition

[17.5](#) Manually provide the inorder, preorder and postorder traversals of the binary search tree of [Fig. 17.20](#).

## Answers to Self-Review Exercises

[17.1](#) a) referential. b) stack. c) predicate. d) first-in, first-out (FIFO). e) link. f) garbage collection. g) queue. h) tree i) last-in, first-out (LIFO). j) binary. k) root. l) child or subtree. m) leaf. n) inorder, preorder, postorder. o) auto-unboxing. p) autoboxing.

[17.2](#) It is possible to insert a node anywhere in a linked list and remove a node from anywhere in a linked list. Nodes in a stack may be inserted only at the top of the stack and removed only from the top.

[17.3](#) A queue is a FIFO data structure that has references to both its head and its tail, so that nodes may be inserted at the tail and deleted from the head. A stack is a LIFO data structure that has a single reference to the top of the stack, where both insertion and deletion of nodes are performed.

[17.4](#)

- Classes allow us to instantiate as many data structure objects of a certain type (i.e., class) as we wish.
- Inheritance enables a subclass to reuse the functionality from a superclass. Public methods of a superclass can be accessed through a subclass to eliminate duplicate logic.
- Composition enables a class to reuse code by storing an instance of another class in a field. Public methods of the member class can be called by methods in the composite class.

[17.5](#) The inorder traversal is

11 18 19 28 32 40 44 49 69 71 72 83 92 97 99

The preorder traversal is

49 28 18 11 19 40 32 44 83 71 69 72 97 92 99

The postorder traversal is

11 19 18 32 44 40 28 69 72 71 92 99 97 83 49

## Exercises

- 17.6 Write a program that concatenates two linked-list objects of characters. Class `ListConcatenate` should include a method `concatenate` that takes references to both list objects as arguments and concatenates the second list to the first list.
- 17.7 Write a program that merges two ordered-list objects of integers into a single ordered-list object of integers. Method `merge` of class `ListMerge` should receive references to each of the list objects to be merged and return a reference to the merged list object.
- 17.8 Write a program that inserts 25 random integers from 0 to 100 in order into a linked-list object. The program should calculate the sum of the elements and the floating-point average of the elements.
- 17.9 Write a program that creates a linked-list object of 10 characters, then creates a second list object containing a copy of the first list, but in reverse order.
- 17.10 Write a program that inputs a line of text and uses a stack object to print the words of the line in reverse order.
- 17.11 Write a program that uses a stack to determine whether a string is a palindrome (i.e., the string is spelled identically backward and forward). The program should ignore spaces and punctuation.
- 17.12 Stacks are used by compilers to help in the process of evaluating expressions and generating machine-language code. In this and the next exercise, we investigate how compilers evaluate arithmetic expressions consisting only of constants, operators and parentheses.

Humans generally write expressions like `3 + 4` and `7 / 9` in which the operator (+ or / here) is written between its operands; this is called *infix notation*. Computers "prefer" *postfix notation*, in which the operator is written to the right of its two operands. The preceding infix expressions would appear in postfix notation as `3 4 +` and `7 9 /`, respectively.

To evaluate a complex infix expression, a compiler would first convert the expression to postfix notation and evaluate the postfix version. Each of these algorithms requires only a single left-to-right pass of the expression. Each algorithm uses a stack object in support of its operation, but each uses the stack for a different purpose.

In this exercise, you will write a Java version of the infix-to-postfix conversion algorithm. In the next exercise, you will write a Java version of the postfix expression evaluation algorithm. In a later exercise, you will discover that code you write in this exercise can help you implement a complete working compiler.

Write class `InfixToPostfixConverter` to convert an ordinary infix arithmetic expression (assume a valid expression is entered) with single-digit integers such as

`(6 + 2) * 5 - 8 / 4`

to a postfix expression. The postfix version of the preceding infix expression is (note that no parentheses are needed)

`6 2 + 5 * 8 4 / -`

The program should read the expression into `StringBuffer infix` and use one of the stack classes implemented in this chapter to help create the postfix expression in `StringBuffer postfix`. The algorithm for creating a postfix expression is as follows:

- a. Push a left parenthesis '(' on the stack.
- b. Append a right parenthesis ')' to the end of `infix`.
- c. While the stack is not empty, read `infix` from left to right and do the following:

If the current character in `infix` is a digit, append it to `postfix`.

If the current character in `infix` is a left parenthesis, push it onto the stack.

If the current character in `infix` is an operator:

Pop operators (if there are any) at the top of the stack while they have equal or higher precedence than the current operator, and append the popped operators to `postfix`.

Push the current character in `infix` onto the stack.

If the current character in `infix` is a right parenthesis:

Pop operators from the top of the stack and append them to `postfix` until a left parenthesis is at the top of the stack.

Pop (and discard) the left parenthesis from the stack.

The following arithmetic operations are allowed in an expression:

- + addition
- subtraction
- \* multiplication
- / division
- ^ exponentiation
- % remainder

The stack should be maintained with stack nodes that each contain an instance variable and a reference to the next stack node. Some of the methods you may want to provide are as follows:

- a. Method `convertToPostfix`, which converts the infix expression to postfix notation.
- b. Method `isOperator`, which determines whether `c` is an operator.
- c. Method `precedence`, which determines whether the precedence of `operator1` (from the infix expression) is less than, equal to or greater than the precedence of `operator2` (from the stack). The method returns `true` if `operator1` has lower precedence than `operator2`. Otherwise, `false` is returned.

- d. Method `stackTop` (this should be added to the stack class), which returns the top value of the stack without popping the stack.

17.13 Write class `PostfixEvaluator`, which evaluates a postfix expression such as

`6 2 + 5 * 8 4 / -`

The program should read a postfix expression consisting of digits and operators into a `StringBuffer`. Using modified versions of the stack methods implemented earlier in this chapter, the program should scan the expression and evaluate it (assume it is valid). The algorithm is as follows:

- a. Append a right parenthesis `' ) '` to the end of the postfix expression. When the right-parenthesis character is encountered, no further processing is necessary.
- b. When the right-parenthesis character has not been encountered, read the expression from left to right.

If the current character is a digit, do the following:

Push its integer value on the stack (the integer value of a digit character is its value in the computer's character set minus the value of `'0'` in Unicode).

Otherwise, if the current character is an *operator*:

Pop the two top elements of the stack into variables `x` and `y`.

Calculate `y operator x`.

Push the result of the calculation onto the stack.

---

[Page 852]

- c. When the right parenthesis is encountered in the expression, pop the top value of the stack. This is the result of the postfix expression.

[*Note:* In b) above (based on the sample expression at the beginning of this exercise), if the operator is `' / '`, the top of the stack is `2` and the next element in the stack is `8`, then pop `2` into `x`, pop `8` into `y`, evaluate `8 / 2` and push the result, `4`, back on the stack. This note also applies to operator `' - '`.] The arithmetic operations allowed in an expression are:

- `+` addition
- `-` subtraction
- `*` multiplication
- `/` division
- `^` exponentiation
- `%` remainder

The stack should be maintained with one of the stack classes introduced in this chapter. You may want to provide the following methods:

- a. Method `evaluatePostfixExpression`, which evaluates the postfix expression.

- b. Method `calculate`, which evaluates the expression `op1 operator op2`.
- c. Method `push`, which pushes a value onto the stack.
- d. Method `pop`, which pops a value off the stack.
- e. Method `isEmpty`, which determines whether the stack is empty.
- f. Method `printStack`, which prints the stack.

17.14 Modify the postfix evaluator program of [Exercise 17.13](#) so that it can process integer operands larger than 9.

17.15 (*Supermarket Simulation*) Write a program that simulates a checkout line at a supermarket. The line is a queue object. Customers (i.e., customer objects) arrive in random integer intervals of from 1 to 4 minutes. Also, each customer is serviced in random integer intervals of from 1 to 4 minutes. Obviously, the rates need to be balanced. If the average arrival rate is larger than the average service rate, the queue will grow infinitely. Even with "balanced" rates, randomness can still cause long lines. Run the supermarket simulation for a 12-hour day (720 minutes), using the following algorithm:

- a. Choose a random integer between 1 and 4 to determine the minute at which the first customer arrives.
- b. At the first customer's arrival time, do the following:
  - Determine customer's service time (random integer from 1 to 4).
  - Begin servicing the customer.
  - Schedule arrival time of next customer (random integer 1 to 4 added to the current time).
- c. For each minute of the day, consider the following:
  - If the next customer arrives, proceed as follows:
    - Say so.
    - Enqueue the customer.
    - Schedule the arrival time of the next customer.
  - If service was completed for the last customer, do the following:
    - Say so.
    - Dequeue next customer to be serviced.
    - Determine customer's service completion time (random integer from 1 to 4 added to the current time).

Now run your simulation for 720 minutes and answer each of the following:

- a. What is the maximum number of customers in the queue at any time?
- b. What is the longest wait any one customer experiences?
- c. What happens if the arrival interval is changed from 1 to 4 minutes to 1 to 3 minutes?

- 17.16 Modify [Fig. 17.17](#) and [Fig. 17.18](#) to allow the binary tree to contain duplicates.
- 17.17 Write a program based on the program of [Fig. 17.17](#) and [Fig. 17.18](#) that inputs a line of text, tokenizes the sentence into separate words (you might want to use the `StreamTokenizer` class from the `java.io` package), inserts the words in a binary search tree and prints the inorder, preorder and postorder traversals of the tree.
- 17.18 In this chapter, we saw that duplicate elimination is straightforward when creating a binary search tree. Describe how you would perform duplicate elimination when using only a one-dimensional array. Compare the performance of array-based duplicate elimination with the performance of binary-search-tree-based duplicate elimination.
- 17.19 Write a method `depth` that receives a binary tree and determines how many levels it has.
- 17.20 (*Recursively Print a List Backward*) Write a method `printListBackward` that recursively outputs the items in a linked list object in reverse order. Write a test program that creates a sorted list of integers and prints the list in reverse order.
- 17.21 (*Recursively Search a List*) Write a method `searchList` that recursively searches a linked list object for a specified value. Method `searchList` should return a reference to the value if it is found; otherwise, `null` should be returned. Use your method in a test program that creates a list of integers. The program should prompt the user for a value to locate in the list.
- 17.22 (*Binary Tree Delete*) In this exercise, we discuss deleting items from binary search trees. The deletion algorithm is not as straightforward as the insertion algorithm. Three cases are encountered when deleting an item: the item is contained in a leaf node (i.e., it has no children), the item is contained in a node that has one child or the item is contained in a node that has two children.

If the item to be deleted is contained in a leaf node, the node is deleted and the reference in the parent node is set to null.

If the item to be deleted is contained in a node with one child, the reference in the parent node is set to reference the child node and the node containing the data item is deleted. This causes the child node to take the place of the deleted node in the tree.

The last case is the most difficult. When a node with two children is deleted, another node in the tree must take its place. However, the reference in the parent node cannot simply be assigned to reference one of the children of the node to be deleted. In most cases, the resulting binary search tree would not embody the following characteristic of binary search trees (with no duplicate values): *The values in any left subtree are less than the value in the parent node, and the values in any right subtree are greater than the value in the parent node.*

Which node is used as a *replacement node* to maintain this characteristic? It is either the node containing the largest value in the tree less than the value in the node being deleted, or the node containing the smallest value in the tree greater than the value in the node being deleted. Let us consider the node with the smaller value. In a binary search tree, the largest value less than a parent's value is located in the left subtree of the parent node and is guaranteed to be contained in the rightmost node of the subtree. This node is located by walking down the left subtree to the right until the reference to the right child of the current node is null. We are now referencing the replacement node, which is either a leaf node or a node with one child to its left. If the replacement node is a leaf node, the steps to perform the deletion are as follows:

- a. Store the reference to the node to be deleted in a temporary reference variable.
- b. Set the reference in the parent of the node being deleted to reference the replacement node.
- c. Set the reference in the parent of the replacement node to `null`.
- d. Set the reference to the right subtree in the replacement node to reference the right subtree of the node to be deleted.
- e. Set the reference to the left subtree in the replacement node to reference the left subtree of the node to be deleted.

---

[Page 854]

The deletion steps for a replacement node with a left child are similar to those for a replacement node with no children, but the algorithm also must move the child into the replacement node's position in the tree. If the replacement node is a node with a left child, the steps to perform the deletion are as follows:

- a. Store the reference to the node to be deleted in a temporary reference variable.
- b. Set the reference in the parent of the node being deleted to reference the replacement node.
- c. Set the reference in the parent of the replacement node reference to the left child of the replacement node.
- d. Set the reference to the right subtree in the replacement node reference to the right subtree of the node to be deleted.
- e. Set the reference to the left subtree in the replacement node to reference the left subtree of the node to be deleted.

Write method `deleteNode`, which takes as its argument the value to delete. Method `deleteNode` should locate in the tree the node containing the value to delete and use the algorithms discussed here to delete the node. If the value is not found in the tree, the method should print a message that indicates whether the value is deleted. Modify the program of [Fig. 17.17](#) and [Fig. 17.18](#) to use this method. After deleting an item, call the methods `inorderTraversal`, `preorderTraversal` and `postorderTraversal` to confirm that the delete operation was performed correctly.

- 17.23 (*Binary Tree Search*) Write method `binaryTreeSearch`, which attempts to locate a specified value in a binary search tree object. The method should take as an argument a search key to be located. If the node containing the search key is found, the method should return a reference to that node; otherwise, it should return a null reference.
- 17.24 (*Level-Order Binary Tree Traversal*) The program of [Fig. 17.17](#) and [Fig. 17.18](#) illustrated three recursive methods of traversing a binary tree: `inorder`, `preorder` and `postorder` traversals. This exercise presents the *level-order traversal* of a binary tree, in which the node values are printed level-by-level, starting at the root node level. The nodes on each level are printed from left to right. The level-order traversal is not a recursive algorithm. It uses a queue object to control the output of the nodes. The algorithm is as follows:

- a. Insert the root node in the queue.
- b. While there are nodes left in the queue, do the following:

Get the next node in the queue.

Print the node's value.

If the reference to the left child of the node is not null:

Insert the left child node in the queue.

If the reference to the right child of the node is not null:

Insert the right child node in the queue.

Write method `levelOrder` to perform a level-order traversal of a binary tree object. Modify the program of [Fig. 17.17](#) and [Fig. 17.18](#) to use this method. [*Note:* You will also need to use queue-processing methods of [Fig. 17.13](#) in this program.]

- 17.25 (*Printing Trees*) Write a recursive method `outputTree` to display a binary tree object on the screen. The method should output the tree row by row, with the top of the tree at the left of the screen and the bottom of the tree toward the right of the screen. Each row is output vertically. For example, the binary tree illustrated in [Fig. 17.20](#) is output as shown in [Fig. 17.21](#).

Figure 17.21. Sample output of recursive method `outputTree`.

(This item is displayed on page 855 in the print version)

Note that the rightmost leaf node appears at the top of the output in the rightmost column and the root node appears at the left of the output. Each column of output starts five spaces to the right of the preceding column. Method `outputTree` should receive an argument `totalSpaces` representing the number of spaces preceding the value to be output. (This variable should start at zero so that the root node is output at the left of the screen.) The method uses a modified inorder traversal to output the tree; it starts at the rightmost node in the tree and works back to the left. The algorithm is as follows:

While the reference to the current node is not null, perform the following:

Recursively call `outputTree` with the right subtree of the current node and `totalSpaces + 5`.

Use a `for` statement to count from 1 to `totalSpaces` and output spaces.

Output the value in the current node.

Set the reference to the current node to refer to the left subtree of the current node.

Increment `totalSpaces` by 5.

[< PREV](#)[NEXT >](#)

## Special Section: Building Your Own Compiler

In [Exercise 7.34](#) and [Exercise 7.35](#), we introduced Simpletron Machine Language (SML), and you implemented a Simpletron computer simulator to execute programs written in SML. In this section, we build a compiler that converts programs written in a high-level programming language to SML. This section "ties" together the entire programming process. You will write programs in this new high-level language, compile them on the compiler you build and run them on the simulator you built in [Exercise 7.35](#). You should make every effort to implement your compiler in an objectoriented manner.

- 17.26 (*The Simple Language*) Before we begin building the compiler, we discuss a simple, yet powerful high-level language similar to early versions of the popular language BASIC. We call the language *Simple*. Every Simple *statement* consists of a *line number* and a Simple *instruction*. Line numbers must appear in ascending order. Each instruction begins with one of the following Simple *commands*: `rem`, `input`, `let`, `print`, `goto`, `if/goto` or `end` (see [Fig. 17.22](#)). All commands except `end` can be used repeatedly. Simple evaluates only integer expressions using the `+`, `-`, `*` and `/` operators. These operators have the same precedence as in Java. Parentheses can be used to change the order of evaluation of an expression.

Figure 17.22. Simple commands.

(This item is displayed on page 856 in the print version)

| Command              | Example statement                    | Description                                                                                                                                                                     |
|----------------------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rem</code>     | 50 <code>rem this is a remark</code> | Any text following the command <code>rem</code> is for documentation purposes only and is ignored by the compiler.                                                              |
| <code>input</code>   | 30 <code>input x</code>              | Display a question mark to prompt the user to enter an integer. Read that integer from the keyboard and store the integer in <code>x</code> .                                   |
| <code>let</code>     | 80 <code>let u = 4 * (j - 56)</code> | Assign <code>u</code> the value of <code>4 * (j - 56)</code> . Note that an arbitrarily complex expression can appear to the right of the equal sign.                           |
| <code>print</code>   | 10 <code>print w</code>              | Display the value of <code>w</code> .                                                                                                                                           |
| <code>goto</code>    | 70 <code>goto 45</code>              | Transfer program control to line 45.                                                                                                                                            |
| <code>if/goto</code> | 35 <code>if i == z goto 80</code>    | Compare <code>i</code> and <code>z</code> for equality and transfer program control to line 80 if the condition is true; otherwise, continue execution with the next statement. |
| <code>end</code>     | 99 <code>end</code>                  | Terminate program execution.                                                                                                                                                    |

Our Simple compiler recognizes only lowercase letters. All characters in a Simple file should be lowercase. (Uppercase letters result in a syntax error unless they appear in a `rem` statement, in which case they are ignored.) A *variable name* is a single letter. Simple does not allow descriptive variable names, so variables should be explained in remarks to indicate their use in a program. Simple uses only integer variables. Simple does not have variable declarations merely mentioning a variable name in a program causes the variable to be

declared and initialized to zero. The syntax of Simple does not allow string manipulation (reading a string, writing a string, comparing strings, etc.). If a string is encountered in a Simple program (after a command other than `rem`), the compiler generates a syntax error. The first version of our compiler assumes that Simple programs are entered correctly. [Exercise 17.29](#) asks the reader to modify the compiler to perform syntax error checking.

---

[Page 856]

Simple uses the conditional `if/goto` and unconditional `goto` statements to alter the flow of control during program execution. If the condition in the `if/goto` statement is true, control is transferred to a specific line of the program. The following relational and equality operators are valid in an `if/goto` statement: `<`, `>`, `<=`, `>=`, `==` or `!=`. The precedence of these operators is the same as in Java.

Let us now consider several programs that demonstrate Simple's features. The first program ([Fig. 17.23](#)) reads two integers from the keyboard, stores the values in variables `a` and `b` and computes and prints their sum (stored in variable `c`).

Figure 17.23. Simple program that determines the sum of two integers.

(This item is displayed on page 857 in the print version)

```
1 10 rem determine and print the sum of two integers
2 15 rem
3 20 rem input the two integers
4 30 input a
5 40 input b
6 45 rem
7 50 rem add integers and store result in c
8 60 let c = a + b
9 65 rem
10 70 rem print the result
11 80 print c
12 90 rem terminate program execution
13 99 end
```

The program of [Fig. 17.24](#) determines and prints the larger of two integers. The integers are input from the keyboard and stored in `s` and `t`. The `if/goto` statement tests the condition `s >= t`. If the condition is true, control is transferred to line 90 and `s` is output; otherwise, `t` is output and control is transferred to the `end` statement in line 99, where the program terminates.

Figure 17.24. Simple program that finds the larger of two integers.

(This item is displayed on page 857 in the print version)

```

1 10 rem determine and print the larger of two integers
2 20 input s
3 30 input t
4 32 rem
5 35 rem test if s >= t
6 40 if s >= t goto 90
7 45 rem
8 50 rem t is greater than s, so print t
9 60 print t
10 70 goto 99
11 75 rem
12 80 rem s is greater than or equal to t, so print s
13 90 print s
14 99 end

```

Simple does not provide a repetition statement (such as Java's `for`, `while` or `do... while`). However, Simple can simulate each of Java's repetition statements by using the `if/goto` and `goto` statements. [Figure 17.25](#) uses a sentinel-controlled loop to calculate the squares of several integers. Each integer is input from the keyboard and stored in variable `j`. If the value entered is the sentinel value `-9999`, control is transferred to line `99`, where the program terminates. Otherwise, `k` is assigned the square of `j`, `k` is output to the screen and control is passed to line `20`, where the next integer is input.

Figure 17.25. Calculate the squares of several integers.

(This item is displayed on page 857 in the print version)

```

1 10 rem calculate the squares of several integers
2 20 input j
3 23 rem
4 25 rem test for sentinel value
5 30 if j == -9999 goto 99
6 33 rem
7 35 rem calculate square of j and assign result to k
8 40 let k = j * j
9 50 print k
10 53 rem
11 55 rem loop to get next j
12 60 goto 20
13 99 end

```

---

[Page 857]

Using the sample programs of [Fig. 17.23](#)[Fig. 17.25](#) as your guide, write a Simple program to accomplish each of the following:

- a. Input three integers, determine their average and print the result.

---

[Page 858]

- b. Use a sentinel-controlled loop to input 10 integers and compute and print their sum.
- c. Use a counter-controlled loop to input 7 integers, some positive and some negative, and compute and print their average.
- d. Input a series of integers and determine and print the largest. The first integer input indicates how many numbers should be processed.
- e. Input 10 integers and print the smallest.
- f. Calculate and print the sum of the even integers from 2 to 30.
- g. Calculate and print the product of the odd integers from 1 to 9.

17.27 (*Building A Compiler. Prerequisites: Complete [Exercise 7.34](#), [Exercise 7.35](#), [Exercise 17.12](#), [Exercise 17.13](#) and [Exercise 17.26](#)*) Now that the Simple language has been presented ([Exercise 17.26](#)), we discuss how to build a Simple compiler. First, we consider the process by which a Simple program is converted to SML and executed by the Simpletron simulator (see [Fig. 17.26](#)). A file containing a Simple program is read by the compiler and converted to SML code. The SML code is output to a file on disk, in which SML instructions appear one per line. The SML file is then loaded into the Simpletron simulator, and the results are sent to a file on disk and to the screen. Note that the Simpletron program developed in [Exercise 7.35](#) took its input from the keyboard. It must be modified to read from a file so it can run the programs produced by our compiler.

Figure 17.26. Writing, compiling and executing a Simple language program.

[\[View full size image\]](#)

The Simple compiler performs two *passes* of the Simple program to convert it to SML. The first pass constructs a *symbol table* (object) in which every *line number* (object), *variable name* (object) and *constant* (object) of the Simple program is stored with its type and corresponding location in the final SML code (the symbol table is discussed in detail below). The first pass also produces the corresponding SML instruction object(s) for each of the Simple statements (object, etc.). If the Simple program contains statements that transfer control to a line later in the program, the first pass results in an SML program containing some "unfinished" instructions. The second pass of the compiler locates and completes the unfinished instructions and outputs the SML program to a file.

## First Pass

The compiler begins by reading one statement of the Simple program into memory. The line must be separated into its individual *tokens* (i.e., "pieces" of a statement) for processing and compilation. (The `StreamTokenizer` class from the `java.io` package can be used.) Recall that every statement begins with a line number followed by a command. As the compiler breaks a statement into tokens, if the token is a line

number, a variable or a constant, it is placed in the symbol table. A line number is placed in the symbol table only if it is the first token in a statement. The `symbolTable` object is an array of `tableEntry` objects representing each symbol in the program. There is no restriction on the number of symbols that can appear in the program. Therefore, the `symbolTable` for a particular program could be large. Make it a 100-element array for now. You can increase or decrease its size once the program is working.

---

[Page 859]

Each `tableEntry` object contains three fields. Field `symbol` is an integer containing the Unicode representation of a variable (remember that variable names are single characters), a line number or a constant. Field `type` is one of the following characters indicating the symbol's type: 'C' for constant, 'L' for line number or 'V' for variable. Field `location` contains the Simpletron memory location (00 to 99) to which the symbol refers. Simpletron memory is an array of 100 integers in which SML instructions and data are stored. For a line number, the location is the element in the Simpletron memory array at which the SML instructions for the Simple statement begin. For a variable or constant, the location is the element in the Simpletron memory array in which the variable or constant is stored. Variables and constants are allocated from the end of Simpletron's memory backward. The first variable or constant is stored at location 99, the next at location 98, etc.

The symbol table plays an integral part in converting Simple programs to SML. We learned in [Chapter 7](#) that an SML instruction is a four-digit integer comprised of two parts: the *operation code* and the *operand*. The operation code is determined by commands in Simple. For example, the simple command `input` corresponds to SML operation code 10 (read), and the Simple command `print` corresponds to SML operation code 11 (write). The operand is a memory location containing the data on which the operation code performs its task (e.g., operation code 10 reads a value from the keyboard and stores it in the memory location specified by the operand). The compiler searches `symbolTable` to determine the Simpletron memory location for each symbol, so the corresponding location can be used to complete the SML instructions.

The compilation of each Simple statement is based on its command. For example, after the line number in a `rem` statement is inserted in the symbol table, the remainder of the statement is ignored by the compiler, because a remark is for documentation purposes only. The `input`, `print`, `goto` and `end` statements correspond to the SML *read*, *write*, *branch* (to a specific location) and *halt* instructions. Statements containing these Simple commands are converted directly to SML. (*Note:* A `goto` statement may contain an unresolved reference if the specified line number refers to a statement further into the Simple program file; this is sometimes called a forward reference.)

When a `goto` statement is compiled with an unresolved reference, the SML instruction must be *flagged* to indicate that the second pass of the compiler must complete the instruction. The flags are stored in a 100-element array `flags` of type `int` in which each element is initialized to -1. If the memory location to which a line number in the Simple program refers is not yet known (i.e., it is not in the symbol table), the line number is stored in array `flags` in the element with the same index as the incomplete instruction. The operand of the incomplete instruction is set to 00 temporarily. For example, an unconditional branch instruction (making a forward reference) is left as +4000 until the second pass of the compiler. The second pass will be described shortly.

Compilation of `if/goto` and `let` statements is more complicated than for other statements; they are the only statements that produce more than one SML instruction. For an `if/goto` statement, the compiler produces code to test the condition and to branch to another line if necessary. The result of the branch could be an unresolved reference. Each of the relational and equality operators can be simulated by using SML's *branch zero* and *branch negative* instructions (or possibly a combination of both).

For a `let` statement, the compiler produces code to evaluate an arbitrarily complex arithmetic expression consisting of integer variables and/or constants. Expressions should separate each operand and operator with spaces. [Exercise 17.12](#) and [Exercise 17.13](#) presented the infix-to-postfix conversion algorithm and the postfix evaluation algorithm used by compilers to evaluate expressions. Before proceeding with your compiler, you should complete each of these exercises. When a compiler encounters an expression, it converts the expression from infix notation to postfix notation, then evaluates the postfix expression.

How is it that the compiler produces the machine language to evaluate an expression containing variables? The postfix evaluation algorithm contains a "hook" where the compiler can generate SML instructions rather

than actually evaluating the expression. To enable this "hook" in the compiler, the postfix evaluation algorithm must be modified to search the symbol table for each symbol it encounters (and possibly insert it), determine the symbol's corresponding memory location and *push the memory location (instead of the symbol) onto the stack*. When an operator is encountered in the postfix expression, the two memory locations at the top of the stack are popped, and machine language for effecting the operation is produced by using the memory locations as operands. The result of each subexpression is stored in a temporary location in memory and pushed back onto the stack so the evaluation of the postfix expression can continue. When postfix evaluation is complete, the memory location containing the result is the only location left on the stack. This is popped, and SML instructions are generated to assign the result to the variable at the left of the `let` statement.

## Second Pass

The second pass of the compiler performs two tasks: Resolve any unresolved references and output the SML code to a file. Resolution of references occurs as follows:

- a. Search the `flags` array for an unresolved reference (i.e., an element with a value other than `-1`).
- b. Locate the object in array `symbolTable` containing the symbol stored in the `flags` array (be sure that the type of the symbol is `'L'` for line number).
- c. Insert the memory location from field `location` into the instruction with the unresolved reference (remember that an instruction containing an unresolved reference has operand `00`).
- d. Repeat *Steps (a), (b) and (c)* until the end of the `flags` array is reached.

After the resolution process is complete, the entire array containing the SML code is output to a disk file with one SML instruction per line. This file can be read by the Simpletron for execution (after the simulator is modified to read its input from a file). Compiling your first Simple program into an SML file and executing that file should give you a real sense of personal accomplishment.

## A Complete Example

The following example illustrates the complete conversion of a Simple program to SML as it will be performed by the Simple compiler. Consider a Simple program that inputs an integer and sums the values from 1 to that integer. The program and the SML instructions produced by the first pass of the Simple compiler are illustrated in [Fig. 17.27](#). The symbol table constructed by the first pass is shown in [Fig. 17.28](#).

Figure 17.27. SML instructions produced after the compiler's first pass.

(This item is displayed on page 861 in the print version)

| Simple program      | SML location and instruction | Description             |
|---------------------|------------------------------|-------------------------|
| 5 rem sum 1 to x    | none                         | rem ignored             |
| 10 input x          | 00 +1099                     | read x into location 99 |
| 15 rem check y == x | none                         | rem ignored             |

| Simple program        | SML location and instruction | Description                        |
|-----------------------|------------------------------|------------------------------------|
| 20 if y == x goto 60  | 01 +2098                     | load y (98) into accumulator       |
|                       | 02 +3199                     | sub x (99) from accumulator        |
|                       | 03 +4200                     | branch zero to unresolved location |
| 25 rem increment y    | none                         | rem ignored                        |
| 30 let y = y + 1      | 04 +2098                     | load y into accumulator            |
|                       | 05 +3097                     | add 1 (97) to accumulator          |
|                       | 06 +2196                     | store in temporary location 96     |
|                       | 07 +2096                     | load from temporary location 96    |
|                       | 08 +2198                     | store accumulator in y             |
| 35 rem add y to total | none                         | rem ignored                        |
| 40 let t = t + y      | 09 +2095                     | load t (95) into accumulator       |
|                       | 10 +3098                     | add y to accumulator               |
|                       | 11 +2194                     | store in temporary location 94     |
|                       | 12 +2094                     | load from temporary location 94    |
|                       | 13 +2195                     | store accumulator in t             |
| 45 rem loop y         | none                         | rem ignored                        |
| 50 goto 20            | 14 +4001                     | branch to location 01              |
| 55 rem output result  | none                         | rem ignored                        |
| 60 print t            | 15 +1195                     | output t to screen                 |
| 99 end                | 16 +4300                     | terminate execution                |

Figure 17.28.  
Symbol table for  
program of [Fig.  
17.27](#).

(This item is displayed on page  
862 in the print version)

| Symbol | Type | Location |
|--------|------|----------|
| 5      | L    | 00       |
| 10     | L    | 00       |
| 'x'    | V    | 99       |

| Symbol | Type | Location |
|--------|------|----------|
| 15     | L    | 01       |
| 20     | L    | 01       |
| 'y'    | V    | 98       |
| 25     | L    | 04       |
| 30     | L    | 04       |
| 1      | C    | 97       |
| 35     | L    | 09       |
| 40     | L    | 09       |
| 't'    | V    | 95       |
| 45     | L    | 14       |
| 50     | L    | 14       |
| 55     | L    | 15       |
| 60     | L    | 15       |
| 99     | L    | 16       |

Most Simple statements convert directly to single SML instructions. The exceptions in this program are remarks, the `if/goto` statement in line 20 and the `let` statements. Remarks do not translate into machine language. However, the line number for a remark is placed in the symbol table in case the line number is referenced in a `goto` statement or an `if/goto` statement. Line 20 of the program specifies that, if the condition `y == x` is true, program control is transferred to line 60. Since line 60 appears later in the program, the first pass of the compiler has not as yet placed 60 in the symbol table. (Statement line numbers are placed in the symbol table only when they appear as the first token in a statement.) Therefore, it is not possible at this time to determine the operand of the SML *branch zero* instruction at location 03 in the array of SML instructions. The compiler places 60 in location 03 of the `flags` array to indicate that the second pass completes this instruction.

We must keep track of the next instruction location in the SML array because there is not a one-to-one correspondence between Simple statements and SML instructions. For example, the `if/goto` statement of line 20 compiles into three SML instructions. Each time an instruction is produced, we must increment the *instruction counter* to the next location in the SML array. Note that the size of Simpletron's memory could present a problem for Simple programs with many statements, variables and constants. It is conceivable that the compiler will run out of memory. To test for this case, your program should contain a *data counter* to keep track of the location at which the next variable or constant will be stored in the SML array. If the value of the instruction counter is larger than the value of the data counter, the SML array is full. In this case, the compilation process should terminate, and the compiler should print an error message indicating that it ran out of memory during compilation. This serves to emphasize that, although the programmer is freed from the burdens of managing memory by the compiler, the compiler itself must carefully determine the placement of instructions and data in memory and must check for such errors as memory being exhausted during the compilation process.

## A Step-by-Step View of the Compilation Process

Let us now walk through the compilation process for the Simple program in [Fig. 17.27](#). The compiler reads the first line of the program

```
5 rem sum 1 to x
```

---

[Page 862]

into memory. The first token in the statement (the line number) is determined using the `StringTokenizer` class. (See [Chapter 29](#) for a discussion of this class.) The token returned by the `StringTokenizer` is converted to an integer by using `static` method `Integer.parseInt()`, so the symbol `5` can be located in the symbol table. If the symbol is not found, it is inserted in the symbol table.

We are at the beginning of the program and this is the first line, and no symbols are in the table yet. Therefore, `5` is inserted into the symbol table as type `L` (line number) and assigned the first location in the SML array (`00`). Although this line is a remark, a space in the symbol table is still allocated for the line number (in case it is referenced by a `goto` or an `if/goto`). No SML instruction is generated for a `rem` statement, so the instruction counter is not incremented.

```
10 input x
```

is tokenized next. The line number `10` is placed in the symbol table as type `L` and assigned the first location in the SML array (`00` because a remark began the program, so the instruction counter is currently `00`). The command `input` indicates that the next token is a variable (only a variable can appear in an `input` statement). `input` corresponds directly to an SML operation code; therefore, the compiler simply has to determine the location of `x` in the SML array. Symbol `x` is not found in the symbol table. So, it is inserted into the symbol table as the Unicode representation of `x`, given type `V` and assigned location `99` in the SML array (data storage begins at `99` and is allocated backward). SML code can now be generated for this statement. Operation code `10` (the SML read operation code) is multiplied by `100`, and the location of `x` (as determined in the symbol table) is added to complete the instruction. The instruction is then stored in the SML array at location `00`. The instruction counter is incremented by one, because a single SML instruction was produced.

---

[Page 863]

The statement

```
15 rem check y == x
```

is tokenized next. The symbol table is searched for line number `15` (which is not found). The line number is inserted as type `L` and assigned the next location in the array, `01`. (Remember that `rem` statements do not produce code, so the instruction counter is not incremented.)

The statement

```
20 if y == x goto 60
```

is tokenized next. Line number `20` is inserted in the symbol table and given type `L` at the next location in the SML array `01`. The command `if` indicates that a condition is to be evaluated. The variable `y` is not found in the symbol table, so it is inserted and given the type `V` and the SML location `98`. Next, SML instructions are generated to evaluate the condition. There is no direct equivalent in SML for the `if/goto`; it must be simulated by performing a calculation using `x` and `y` and branching according to the result. If `y` is equal to `x`,

the result of subtracting  $x$  from  $y$  is zero, so the *branch zero* instruction can be used with the result of the calculation to simulate the *if/goto* statement. The first step requires that  $y$  be loaded (from SML location 98) into the accumulator. This produces the instruction 01 +2098. Next,  $x$  is subtracted from the accumulator. This produces the instruction 02 +3199. The value in the accumulator may be zero, positive or negative. The operator is  $==$ , so we want to *branch zero*. First, the symbol table is searched for the branch location (60 in this case), which is not found. So, 60 is placed in the *flags* array at location 03, and the instruction 03 +4200 is generated. (We cannot add the branch location because we have not yet assigned a location to line 60 in the SML array.) The instruction counter is incremented to 04.

The compiler proceeds to the statement

```
25 rem increment y
```

The line number 25 is inserted in the symbol table as type *L* and assigned SML location 04. The instruction counter is not incremented.

When the statement

```
30 let y = y + 1
```

is tokenized, the line number 30 is inserted in the symbol table as type *L* and assigned SML location 04. Command *let* indicates that the line is an assignment statement. First, all the symbols on the line are inserted in the symbol table (if they are not already there). The integer 1 is added to the symbol table as type *C* and assigned SML location 97. Next, the right side of the assignment is converted from infix to postfix notation. Then the postfix expression ( $y\ 1\ +$ ) is evaluated. Symbol  $y$  is located in the symbol table, and its corresponding memory location is pushed onto the stack. Symbol 1 is also located in the symbol table, and its corresponding memory location is pushed onto the stack. When the operator  $+$  is encountered, the postfix evaluator pops the stack into the right operand of the operator and pops the stack again into the left operand of the operator, then produces the SML instructions

```
04 +2098 (load y)
```

```
05 +3097 (add 1)
```

The result of the expression is stored in a temporary location in memory (96) with instruction

```
06 +2196 (store temporary)
```

and the temporary location is pushed onto the stack. Now that the expression has been evaluated, the result must be stored in  $y$  (i.e., the variable on the left side of  $=$ ). So, the temporary location is loaded into the accumulator and the accumulator is stored in  $y$  with the instructions

```
07 +2096 (load temporary)
```

```
08 +2198 (store y)
```

The reader should immediately notice that SML instructions appear to be redundant. We will discuss this issue shortly.

When the statement

```
35 rem add y to total
```

is tokenized, line number 35 is inserted in the symbol table as type L and assigned location 09.

The statement

```
40 let t = t + y
```

is similar to line 30. The variable t is inserted in the symbol table as type V and assigned SML location 95. The instructions follow the same logic and format as line 30, and the instructions 09 +2095, 10 +3098, 11 +2194, 12 +2094 and 13 +2195 are generated. Note that the result of t + y is assigned to temporary location 94 before being assigned to t (95). Once again, the reader should note that the instructions in memory locations 11 and 12 appear to be redundant. Again, we will discuss this shortly.

The statement

```
45 rem loop y
```

is a remark, so line 45 is added to the symbol table as type L and assigned SML location 14.

The statement

```
50 goto 20
```

transfers control to line 20. Line number 50 is inserted in the symbol table as type L and assigned SML location 14. The equivalent of goto in SML is the *unconditional branch* (40) instruction that transfers control to a specific SML location. The compiler searches the symbol table for line 20 and finds that it corresponds to SML location 01. The operation code (40) is multiplied by 100, and location 01 is added to it to produce the instruction 14 +4001.

The statement

```
55 rem output result
```

is a remark, so line 55 is inserted in the symbol table as type L and assigned SML location 15.

The statement

```
60 print t
```

is an output statement. Line number 60 is inserted in the symbol table as type L and assigned SML location 15. The equivalent of print in SML is operation code 11 (*write*). The location of t is determined from the symbol table and added to the result of the operation code multiplied by 100.

The statement

is the final line of the program. Line number 99 is stored in the symbol table as type `L` and assigned SML location 16. The `end` command produces the SML instruction `+4300` (43 is *halt* in SML), which is written as the final instruction in the SML memory array.

This completes the first pass of the compiler. We now consider the second pass. The `flags` array is searched for values other than `-1`. Location 03 contains 60, so the compiler knows that instruction 03 is incomplete. The compiler completes the instruction by searching the symbol table for 60, determining its location and adding the location to the incomplete instruction. In this case, the search determines that line 60 corresponds to SML location 15, so the completed instruction 03 `+4215` is produced, replacing 03 `+4200`. The Simple program has now been compiled successfully.

To build the compiler, you will have to perform each of the following tasks:

- a. Modify the Simpletron simulator program you wrote in [Exercise 7.35](#) to take its input from a file specified by the user (see [Chapter 14](#)). The simulator should output its results to a disk file in the same format as the screen output. Convert the simulator to be an object-oriented program. In particular, make each part of the hardware an object. Arrange the instruction types into a class hierarchy using inheritance. Then execute the program polymorphically simply by telling each instruction to execute itself with an `executeInstruction` message.

---

[Page 865]

- b. Modify the infix-to-postfix evaluation algorithm of [Exercise 17.12](#) to process multidigit integer operands and single-letter variable name operands. [*Hint:* Class `StringTokenizer` can be used to locate each constant and variable in an expression, and constants can be converted from strings to integers by using `Integer` class method `parseInt`.] [*Note:* The data representation of the postfix expression must be altered to support variable names and integer constants.]
- c. Modify the postfix evaluation algorithm to process multidigit integer operands and variable name operands. Also, the algorithm should now implement the "hook" discussed earlier so that SML instructions are produced rather than directly evaluating the expression. [*Hint:* Class `StringTokenizer` can be used to locate each constant and variable in an expression, and constants can be converted from strings to integers by using `Integer` class method `parseInt`.] [*Note:* The data representation of the postfix expression must be altered to support variable names and integer constants.]
- d. Build the compiler. Incorporate parts b) and c) for evaluating expressions in `let` statements. Your program should contain a method that performs the first pass of the compiler and a method that performs the second pass of the compiler. Both methods can call other methods to accomplish their tasks. Make your compiler as object oriented as possible.

17.28 (*Optimizing the Simple Compiler*) When a program is compiled and converted into SML, a set of instructions is generated. Certain combinations of instructions often repeat themselves, usually in triplets called *productions*. A production normally consists of three instructions, such as *load*, *add* and *store*. For example, [Fig. 17.29](#) illustrates five of the SML instructions that were produced in the compilation of the program in [Fig. 17.27](#). The first three instructions are the production that adds 1 to `y`. Note that instructions 06 and 07 store the accumulator value in temporary location 96, then load the value back into the accumulator so instruction 08 can store the value in location 98. Often a production is followed by a load instruction for the same location that was just stored. This code can be *optimized* by eliminating the store instruction and the subsequent load instruction that operate on the same memory location, thus enabling the Simpletron to execute the program faster. [Figure 17.30](#) illustrates the optimized SML for the program of [Fig. 17.27](#). Note that there are four fewer instructions in the optimized code a memory-space savings of 25%.

Figure 17.29.  
Unoptimized  
code from the  
program of Fig.  
19.25.

```

1 04 +2098 (load)
2 05 +3097 (add)
3 06 +2196 (store)
4 07 +2096 (load)
5 08 +2198 (store)

```

Figure 17.30. Optimized code for the program of [Fig. 17.27](#).

(This item is displayed on page 866 in the print version)

| Simple program        | SML location and instruction | Description                   |
|-----------------------|------------------------------|-------------------------------|
| 5 rem sum 1 to x      | <i>none</i>                  | rem ignored                   |
| 10 input x            | 00 +1099                     | read x into location 99       |
| 15 rem check y == x   | <i>none</i>                  | rem ignored                   |
| 20 if y == x goto 60  | 01 +2098                     | load y (98) into accumulator  |
|                       | 02 +3199                     | sub x (99) from accumulator   |
|                       | 03 +4211                     | branch to location 11 if zero |
| 25 rem increment y    | <i>none</i>                  | rem ignored                   |
| 30 let y = y + 1      | 04 +2098                     | load y into accumulator       |
|                       | 05 +3097                     | add 1 (97) to accumulator     |
|                       | 06 +2198                     | store accumulator in y (98)   |
| 35 rem add y to total | <i>none</i>                  | rem ignored                   |
| 40 let t = t + y      | 07 +2096                     | load t from location (96)     |
|                       | 08 +3098                     | add y (98) accumulator        |
|                       | 09 +2196                     | store accumulator in t (96)   |
| 45 rem loop y         | <i>none</i>                  | rem ignored                   |
| 50 goto 20            | 10 +4001                     | branch to location 01         |
| 55 rem output result  | <i>none</i>                  | rem ignored                   |
| 60 print t            | 11 +1196                     | output t (96) to screen       |
| 99 end                | 12 +4300                     | terminate execution           |

17.29 (*Modifications to the Simple Compiler*) Perform the following modifications to the Simple compiler. Some of these modifications might also require modifications to the Simpletron simulator program written in [Exercise 7.35](#).

- a. Allow the remainder operator (%) to be used in `let` statements. Simpletron Machine Language must be modified to include a remainder instruction.
- b. Allow exponentiation in a `let` statement using ^ as the exponentiation operator. Simpletron Machine Language must be modified to include an exponentiation instruction.

---

[Page 866]

- c. Allow the compiler to recognize uppercase and lowercase letters in Simple statements (e.g., `'A'` is equivalent to `'a'`). No modifications to the Simpletron simulator are required.
- d. Allow `input` statements to read values for multiple variables such as `input x, y`. No modifications to the Simpletron simulator are required to perform this enhancement to the Simple compiler.
- e. Allow the compiler to output multiple values from a single `print` statement, such as `print a, b, c`. No modifications to the Simpletron simulator are required to perform this enhancement.
- f. Add syntax-checking capabilities to the compiler so error messages are output when syntax errors are encountered in a Simple program. No modifications to the Simpletron simulator are required.
- g. Allow arrays of integers. No modifications to the Simpletron simulator are required to perform this enhancement.
- h. Allow subroutines specified by the Simple commands `gosub` and `return`. Command `gosub` passes program control to a subroutine and command `return` passes control back to the statement after the `gosub`. This is similar to a method call in Java. The same subroutine can be called from many `gosub` commands distributed throughout a program. No modifications to the Simpletron simulator are required.

---

[Page 867]

- i. Allow repetition statements of the form

```
for x = 2 to 10 step 2
 Simple statements
next
```

This `for` statement loops from 2 to 10 with an increment of 2. The `next` line marks the end of the body of the `for` line. No modifications to the Simpletron simulator are required.

- j. Allow repetition statements of the form

```
for x = 2 to 10
 Simple statements
next
```

This `for` statement loops from 2 to 10 with a default increment of 1. No modifications to

the Simpletron simulator are required.

- k. Allow the compiler to process string input and output. This requires the Simpletron simulator to be modified to process and store string values. [*Hint:* Each Simpletron word (i.e., memory location) can be divided into two groups, each holding a two-digit integer. Each two-digit integer represents the Unicode decimal equivalent of a character. Add a machine-language instruction that will print a string beginning at a certain Simpletron memory location. The first half of the Simpletron word at that location is a count of the number of characters in the string (i.e., the length of the string). Each succeeding half word contains one Unicode character expressed as two decimal digits. The machine-language instruction checks the length and prints the string by translating each two-digit number into its equivalent character.]
- l. Allow the compiler to process floating-point values in addition to integers. The Simpletron Simulator must also be modified to process floating-point values.

17.30 (*A Simple Interpreter*) An interpreter is a program that reads a high-level language program statement, determines the operation to be performed by the statement and executes the operation immediately. The high-level language program is not converted into machine language first. Interpreters execute more slowly than compilers do, because each statement encountered in the program being interpreted must first be deciphered at execution time. If statements are contained in a loop, the statements are deciphered each time they are encountered in the loop. Early versions of the BASIC programming language were implemented as interpreters. Most Java programs are run interpretively.

Write an interpreter for the Simple language discussed in [Exercise 17.26](#). The program should use the infix-to-postfix converter developed in [Exercise 17.12](#) and the postfix evaluator developed in [Exercise 17.13](#) to evaluate expressions in a `let` statement. The same restrictions placed on the Simple language in [Exercise 17.26](#) should be adhered to in this program. Test the interpreter with the Simple programs written in [Exercise 17.26](#). Compare the results of running these programs in the interpreter with the results of compiling the Simple programs and running them in the Simpletron simulator built in [Exercise 7.35](#).

17.31 (*Insert/Delete Anywhere in a Linked List*) Our linked-list class allowed insertions and deletions at only the front and the back of the linked list. These capabilities were convenient for us when we used inheritance or composition to produce a stack class and a queue class with a minimal amount of code simply by reusing the list class. Linked lists are normally more general than those we provided. Modify the linked-list class we developed in this chapter to handle insertions and deletions anywhere in the list.

17.32 (*Lists and Queues without Tail References*) Our implementation of a linked list ([Fig. 17.3](#)) used both a `firstNode` and a `lastNode`. The `lastNode` was useful for the `insertAtBack` and `removeFromBack` methods of the `List` class. The `insertAtBack` method corresponds to the `enqueue` method of the `Queue` class.

---

[Page 868]

Rewrite the `List` class so that it does not use a `lastNode`. Thus, any operations on the tail of a list must begin searching the list from the front. Does this affect our implementation of the `Queue` class ([Fig. 17.13](#))?

17.33 (*Performance of Binary Tree Sorting and Searching*) One problem with the binary tree sort is that the order in which the data is inserted affects the shape of the tree for the same collection of data, different orderings can yield binary trees of dramatically different shapes. The performance of the binary tree sorting and searching algorithms is sensitive to the shape of the binary tree. What shape would a binary tree have if its data were inserted in increasing order? in decreasing order? What shape should the tree have to achieve maximal searching performance?

17.34 (*Indexed Lists*) As presented in the text, linked lists must be searched sequentially. For large

lists, this can result in poor performance. A common technique for improving list-searching performance is to create and maintain an index to the list. An index is a set of references to key places in the list. For example, an application that searches a large list of names could improve performance by creating an index with 26 entries one for each letter of the alphabet. A search operation for a last name beginning with 'Y' would then first search the index to determine where the 'Y' entries begin, then "jump into" the list at that point and search linearly until the desired name is found. This would be much faster than searching the linked list from the beginning. Use the `List` class of [Fig. 17.3](#) as the basis of an `IndexedList` class.

Write a program that demonstrates the operation of indexed lists. Be sure to include methods `insertInIndexedList`, `searchIndexedList` and `deleteFromIndexedList`.

17.35 In [Section 17.7](#), we created a stack class from class `List` with inheritance ([Fig. 17.10](#)) and

# Chapter 18. Generics

*Every man of genius sees the world at a different angle from his fellows.*

Havelock Ellis

*...our special individuality, as distinguished from our generic humanity.*

Oliver Wendell Holmes, Sr.

*Born under one law, to another bound.*

Lord Brooke

*You deal in the raw material of opinion, and, if my convictions have any validity, opinion ultimately governs the world.*

Woodrow Wilson

## OBJECTIVES

In this chapter you will learn:

- To create generic methods that perform identical tasks on arguments of different types.
- To create a generic `Stack` class that can be used to store objects of any class or interface type.
- To understand how to overload generic methods with non-generic methods or with other generic methods.
- To understand raw types and how they help achieve backwards compatibility.
- To use wildcards when precise type information about a parameter is not required in the method body.
- The relationship between generics and inheritance.

## Outline

## 18.1. Introduction

It would be nice if we could write a single `sort` method that could sort the elements in an `Integer` array, a `String` array or an array of any type that supports ordering (i.e., its elements can be compared). It would also be nice if we could write a single `Stack` class that could be used as a `Stack` of integers, a `Stack` of floating-point numbers, a `Stack` of `Strings` or a `Stack` of any other type. It would be even nicer if we could detect type mismatches at compile time known as [compile-time type safety](#). For example, if a `Stack` stores only integers, attempting to push a `String` on to that `Stack` should issue a compile-time error.

This chapter discusses one of J2SE 5.0's new features [generics](#) which provides the means to create the general models mentioned above. [Generic methods](#) and [generic classes](#) enable programmers to specify, with a single method declaration, a set of related methods or, with a single class declaration, a set of related types, respectively. Generics also provide compile-time type safety that allows programmers to catch invalid types at compile time.

We might write a generic method for sorting an array of objects, then invoke the generic method with `Integer` arrays, `Double` arrays, `String` arrays and so on, to sort the array elements. The compiler could perform type checking to ensure that the array passed to the sorting method contains same type elements. We might write a single generic `Stack` class that manipulates a stack of objects, then instantiate `Stack` objects for a stack of `Integers`, a stack of `Doubles`, a stack of `Strings` and so on. The compiler could perform type checking to ensure that the `Stack` stores elements of the same type.

### Software Engineering Observation 18.1

*Generic methods and classes are among Java's most powerful capabilities for software reuse with compile-time type safety.*

This chapter presents generic method and generic class examples. It also considers the relationships between generics and other Java features, such as overloading and inheritance. [Chapter 19](#), Collections, presents an in-depth treatment of the Java Collections Framework's generic methods and classes. A collection is a data structure that maintains references to many objects. The Java Collections Framework uses generics to allow programmers to specify the exact types of objects that a particular collection will store in a program.

## 18.2. Motivation for Generic Methods

Overloaded methods are often used to perform similar operations on different types of data. To motivate generic methods, let's begin with an example ([Fig. 18.1](#)) that contains three overloaded `printArray` methods (lines 714, lines 1724 and lines 2734). These methods print the string representations of the elements of an `Integer` array, a `Double` array and a `Character` array, respectively. Note that we could have used arrays of primitive types `int`, `double` and `char` in this example. We chose to use arrays of type `Integer`, `Double` and `Character` to set up our generic method example, because only reference types can be used with generic methods and classes.

Figure 18.1. Printing array elements using overloaded methods.

(This item is displayed on pages 871 - 872 in the print version)

```
1 // Fig. 18.1: OverloadedMethods.java
2 // Using overloaded methods to print array of different types.
3
4 public class OverloadedMethods
5 {
6 // method printArray to print Integer array
7 public static void printArray(Integer[] inputArray)
8 {
9 // display array elements
10 for (Integer element : inputArray)
11 System.out.printf("%s ", element);
12
13 System.out.println();
14 } // end method printArray
15
16 // method printArray to print Double array
17 public static void printArray(Double[] inputArray)
18 {
19 // display array elements
20 for (Double element : inputArray)
21 System.out.printf("%s ", element);
22
23 System.out.println();
24 } // end method printArray
25
26 // method printArray to print Character array
27 public static void printArray(Character[] inputArray)
28 {
29 // display array elements
30 for (Character element : inputArray)
31 System.out.printf("%s ", element);
32
33 System.out.println();
34 } // end method printArray
35
36 public static void main(String args[])
37 {
38 // create arrays of Integer, Double and Character
```

```

39 Integer[] integerArray = { 1, 2, 3, 4, 5, 6 };
40 Double[] doubleArray = { 1.1, 2.2, 3.3, 4.4, 5.5, 6.6, 7.7 };
41 Character[] characterArray = { 'H', 'E', 'L', 'L', 'O' };
42
43 System.out.println("Array integerArray contains:");
44 printArray(integerArray); // pass an Integer array
45 System.out.println("\nArray doubleArray contains:");
46 printArray(doubleArray); // pass a Double array
47 System.out.println("\nArray characterArray contains:");
48 printArray(characterArray); // pass a Character array
49 } // end main
50 } // end class OverloadedMethods

```

```

Array integerArray contains:
1 2 3 4 5 6

Array doubleArray contains:
1.1 2.2 3.3 4.4 5.5 6.6 7.7

Array characterArray contains:
H E L L O

```

[Page 872]

The program begins by declaring and initializing three arrays: six-element `Integer` array `integerArray` (line 39), seven-element `Double` array `doubleArray` (line 40) and five-element `Character` array `characterArray` (line 41). Then, lines 43-48 output the arrays.

When the compiler encounters a method call, it always attempts to locate a method declaration that has the same method name and parameters that match the argument types in the method call. In this example, each `printArray` call exactly matches one of the `printArray` method declarations. For example, line 44 calls `printArray` with `integerArray` as its argument. At compile time, the compiler determines argument `integerArray`'s type (i.e., `Integer[]`) and attempts to locate a method named `printArray` that specifies a single `Integer[]` parameter (lines 71-74) and sets up a call to that method. Similarly, when the compiler encounters the `printArray` call at line 46, it determines argument `doubleArray`'s type (i.e., `Double[]`), then attempts to locate a method named `printArray` that specifies a single `Double[]` parameter (lines 172-174) and sets up a call to that method. Finally, when the compiler encounters the `printArray` call at line 48, it determines argument `characterArray`'s type (i.e., `Character[]`), then attempts to locate a method named `printArray` that specifies a single `Character[]` parameter (lines 273-274) and sets up a call to that method.

Study each `printArray` method. Note that the array element type appears in two locations in each method: the method header (lines 7, 17 and 27) and the `for` statement header (lines 10, 20 and 30). If we replace the element types in each method with a generic name by convention we'll use `E` to represent the "element" type then all three methods would look like the one in [Fig. 18.2](#). It appears that if we can replace the array element type in each of the three methods with a single generic type, then we should be able to declare one `printArray` method that can display the string representations of the elements of any array that contains objects. Note that the format specifier `%s` can be used to output any object's string representation; the object's `toString` method will be called implicitly. The method in [Fig. 18.2](#) is similar to the generic `printArray` method declaration we discuss in [Section 18.3](#).

Figure 18.2. `printArray` method in which actual type names are replaced by

convention with the generic name **E**.

(This item is displayed on page 873 in the print version)

```
1 public static void printArray(E[] inputArray)
2 {
3 // display array elements
4 for (E element : inputArray)
5 System.out.printf("%s ", element);
6
7 System.out.println();
8 } // end method printArray
```

## 18.3. Generic Methods: Implementation and Compile-Time Translation

If the operations performed by several overloaded methods are identical for each argument type, the overloaded methods can be more compactly and conveniently coded using a generic method. You can write a single generic method declaration that can be called with arguments of different types. Based on the types of the arguments passed to the generic method, the compiler handles each method call appropriately.

[Figure 18.3](#) reimplements the application of [Fig. 18.1](#) using a generic `printArray` method (lines 714). Note that the `printArray` method calls in lines 24, 26 and 28 are identical to those of [Fig. 18.1](#) (lines 44, 46 and 48) and that the outputs of the two applications are identical. This dramatically demonstrates the expressive power of generics.

Figure 18.3. Printing array elements using generic method `printArray`.

(This item is displayed on page 874 in the print version)

```
1 // Fig. 18.3: GenericMethodTest.java
2 // Using generic methods to print array of different types.
3
4 public class GenericMethodTest
5 {
6 // generic method printArray
7 public static < E > void printArray(E[] inputArray)
8 {
9 // display array elements
10 for (E element : inputArray)
11 System.out.printf("%s ", element);
12
13 System.out.println();
14 } // end method printArray
15
16 public static void main(String args[])
17 {
18 // create arrays of Integer, Double and Character
19 Integer[] intArray = { 1, 2, 3, 4, 5 };
20 Double[] doubleArray = { 1.1, 2.2, 3.3, 4.4, 5.5, 6.6, 7.7 };
21 Character[] charArray = { 'H', 'E', 'L', 'L', 'O' };
22
23 System.out.println("Array integerArray contains:");
24 printArray(integerArray); // pass an Integer array
25 System.out.println("\nArray doubleArray contains:");
26 printArray(doubleArray); // pass a Double array
27 System.out.println("\nArray characterArray contains:");
28 printArray(characterArray); // pass a Character array
29 } // end main
30 } // end class GenericMethodTest
```

```
Array integerArray contains:
1 2 3 4 5 6

Array doubleArray contains:
1.1 2.2 3.3 4.4 5.5 6.6 7.7

Array characterArray contains:
H E L L O
```

Line 7 begins method `printArray`'s declaration. All generic method declarations have a **type parameter section** delimited by **angle brackets** (`<` and `>`) that precedes the method's return type (`< E >` in this example). Each type parameter section contains one or more **type parameters** (also called **formal type parameters**), separated by commas. A type parameter, also known as a **type variable**, is an identifier that specifies a generic type name. The type parameters can be used to declare the return type, parameter types and local variable types in a generic method declaration, and act as placeholders for the types of the arguments passed to the generic method, which are known as **actual type arguments**. A generic method's body is declared like that of any other method. Note that type parameters can represent only reference types not primitive types (like `int`, `double` and `char`). Note, too, that the type parameter names throughout the method declaration must match those declared in the type parameter section. For example, line 10 declares `element` as type `E`, which matches the type parameter (`E`) declared in line 7. Also, a type parameter can be declared only once in the type parameter section but can appear more than once in the method's parameter list. For example, the type parameter name `E` appears twice in the following method's parameter list:

```
public static < E > void printTwoArrays(E[] array1, E[] array2)
```

Type parameter names need not be unique among different generic methods.

## Common Programming Error 18.1

*When declaring a generic method, failing to place a type parameter section before the return type of a method is a syntax error the compiler will not understand the type parameter name when it is encountered in the method.*

Method `printArray`'s type parameter section declares type parameter, `E`, as the placeholder for the array element type that `printArray` will output. Note that `E` appears in the parameter list as the array element type (line 7). The `for` statement header (line 10) also uses `E` as the element type. These are the same two locations where the overloaded `printArray` methods of [Fig. 18.1](#) specified `Integer`, `Double` or `Character` as the array element type. The remainder of `printArray` is identical to the versions presented in [Fig. 18.1](#).

## Good Programming Practice 18.1

*It is recommended that type parameters be specified as individual capital letters. Typically, a type parameter that represents the type of an element in an array (or other collection) is named **E** for "element."*

---

[Page 875]

As in [Fig. 18.1](#), the program begins by declaring and initializing six-element `Integer` array `integerArray` (line 19), seven-element `Double` array `doubleArray` (line 20) and five-element `Character` array `characterArray` (line 21). Then the program outputs each array by calling `printArray` (lines 24, 26 and 28) once with argument `integerArray`, once with argument `doubleArray` and once with argument `characterArray`.

When the compiler encounters line 24, it first determines argument `integerArray`'s type (i.e., `Integer[]`) and attempts to locate a method named `printArray` that specifies a single `Integer[]` parameter. There is no such method in this example. Next, the compiler determines whether there is a generic method named `printArray` that specifies a single array parameter and uses a type parameter to represent the array element type. The compiler determines that method `printArray` (lines 714) is a match and sets up a call to the method. The same process is repeated for the calls to method `printArray` at lines 26 and 28.

## Common Programming Error 18.2

*If the compiler cannot match a method call to a non-generic or a generic method declaration, a compilation error occurs.*

## Common Programming Error 18.3

*If the compiler does not find a method declaration that matches a method call exactly, but does find two or more generic methods that can satisfy the method call, a compilation error occurs.*

In addition to setting up the method calls, the compiler also determines whether the operations in the method body can be applied to elements of the type stored in the array argument. The only operation performed on the array elements in this example is to output the string representation of the elements. Line 11 performs an implicit `toString` call on every `element`. To work with generics, every element of the array must be an object of a class or interface type. Since all objects have a `toString` method, the compiler is satisfied that line 11 performs a valid operation for any object in `printArray`'s array argument. The `toString` methods of classes `Integer`, `Double` and `Character` return the string representation of the underlying `int`, `double` or `char` value, respectively.

When the compiler translates generic method `printArray` into Java bytecodes, it removes the type parameter section and replaces the type parameters with actual types. This process is known as **erasure**. By default all generic types are replaced with type `Object`. So the compiled version of method `printArray`

appears as shown in [Fig. 18.4](#) there is only one copy of this code that is used for all `printArray` calls in the example. This is quite different from other, similar mechanisms, such as C++'s templates in which a separate copy of the source code is generated and compiled for every type passed as an argument to the method. As we will discuss in [Section 18.4](#), the translation and compilation of generics is a bit more involved than what we have discussed in this section.

Figure 18.4. Generic method `printArray` after erasure is performed by the compiler.

(This item is displayed on page 876 in the print version)

```
1 public static void printArray(Object[] inputArray)
2 {
3 // display array elements
4 for (Object element : inputArray)
5 System.out.printf("%s ", element);
6
7 System.out.println();
8 } // end method printArray
```

By declaring `printArray` as a generic method in [Fig. 18.3](#), we eliminated the need for the overloaded methods of [Fig. 18.1](#), saving 20 lines of code and creating a reusable method that can output the string representations of the elements in any array that contains objects. However, this particular example could have simply declared the `printArray` method as shown in [Fig. 18.4](#) using an `Object` array as the parameter. This would have yielded the same results because any `Object` can be output as a `String`. In a generic method, the benefits become apparent when the method also uses a type parameter as the method's return type, as we demonstrate in the next section.

## 18.4. Additional Compile-Time Translation Issues: Methods That Use a Type Parameter as the Return Type

Let's consider a generic method example in which type parameters are used in the return type and in the parameter list (Fig. 18.5). The application uses a generic method `maximum` to determine and return the largest of its three arguments of the same type. Unfortunately, the relational operator `>` cannot be used with reference types. However, it is possible to compare two objects of the same class if that class implements the generic interface `Comparable< T >` (package `java.lang`). All the type-wrapper classes for primitive types implement this interface. Like generic classes, **generic interfaces** enable programmers to specify, with a single interface declaration, a set of related types. `Comparable< T >` objects have a `compareTo` method. For example, if we have two `Integer` objects, `integer1` and `integer2`, they can be compared with the expression:

```
integer1.compareTo(integer2)
```

Figure 18.5. Generic method `maximum` with an upper bound on its type parameter.

(This item is displayed on page 877 in the print version)

```

1 // Fig. 18.5: MaximumTest.java
2 // Generic method maximum returns the largest of three objects.
3
4 public class MaximumTest
5 {
6 // determines the largest of three Comparable objects
7 public static < T extends Comparable< T > > T maximum(T x, T y, T z)
8 {
9 T max = x; // assume x is initially the largest
10
11 if (y.compareTo(max) > 0)
12 max = y; // y is the largest so far
13
14 if (z.compareTo(max) > 0)
15 max = z; // z is the largest
16
17 return max; // returns the largest object
18 } // end method maximum
19
20 public static void main(String args[])
21 {
22 System.out.printf("Maximum of %d, %d and %d is %d\n\n", 3, 4, 5,
23 maximum(3, 4, 5));
24 System.out.printf("Maximum of %.1f, %.1f and %.1f is %.1f\n\n",
25 6.6, 8.8, 7.7, maximum(6.6, 8.8, 7.7));
26 System.out.printf("Maximum of %s, %s and %s is %s\n", "pear",
27 "apple", "orange", maximum("pear", "apple", "orange"));
28 } // end main
29 } // end class MaximumTest

```

```
Maximum of 3, 4 and 5 is 5

Maximum of 6.6, 8.8 and 7.7 is 8.8

Maximum of pear, apple and orange is pear
```

It is the responsibility of the programmer who declares a class that implements `Comparable< T >` to declare method `compareTo` such that it compares the contents of two objects of that class and returns the results of the comparison. The method must return 0 if the objects are equal, -1 if `object1` is less than `object2` or 1 if `object1` is greater than `object2`. For example, class `Integer`'s `compareTo` method compares the `int` values stored in two `Integer` objects. A benefit of implementing interface `Comparable< T >` is that `Comparable< T >` objects can be used with the sorting and searching methods of class `Collections` (package `java.util`). We discuss those methods in [Chapter 19](#), Collections. In this example, we'll use method `compareTo` in method `maximum` to help determine the largest value.

Generic method `maximum` (lines 718) uses type parameter `T` as the return type of the method (line 7), as the type of method parameters `x`, `y` and `z` (line 7), and as the type of local variable `max` (line 9). The type parameter section specifies that `T` extends `Comparable< T >` only objects of classes that implement interface `Comparable< T >` can be used with this method. In this case, `Comparable` is known as the **upper bound** of the type parameter. By default, `Object` is the upper bound. Note that type parameter declarations that **bound** the parameter always use keyword `extends` regardless of whether the type parameter extends a class or implements an interface. This type parameter is more restrictive than the type parameter specified for `printArray` in [Fig. 18.3](#), which was able to output arrays containing any type of object. The restriction of using `Comparable< T >` objects is important because not all objects can be compared. However, `Comparable< T >` objects are guaranteed to have a `compareTo` method.

---

[Page 877]

Method `maximum` uses the same algorithm that we used in [Section 6.4](#) to determine the largest of its three arguments. The method assumes that its first argument (`x`) is the largest and assigns it to local variable `max` (line 9). Next, the `if` statement at lines 1112 determines whether `y` is greater than `max`. The condition invokes `y`'s `compareTo` method with the expression `y.compareTo( max )`, which returns -1, 0 or 1, to determine `y`'s relationship to `max`. If the return value of the `compareTo` is greater than 0, then `y` is greater and is assigned to variable `max`. Similarly, the `if` statement at lines 1415 determines whether `z` is greater than `max`. If so, line 15 assigns `z` to `max`. Then, line 17 returns `max` to the caller.

In `main` (lines 2028), line 23 calls `maximum` with the integers 3, 4 and 5. When the compiler encounters this call, it first looks for a `maximum` method that takes three arguments of type `int`. There is no such method, so the compiler looks for a generic method that can be used and finds generic method `maximum`. However, recall that the arguments to a generic method must be of a reference type. So the compiler autoboxes the three `int` values as `Integer` objects and specifies that the three `Integer` objects will be passed to `maximum`. Note that class `Integer` (package `java.lang`) implements interface `Comparable< Integer >` such that method `compareTo` compares the `int` values in two `Integer` objects. Therefore, `Integers` are valid arguments to method `maximum`. When the `Integer` representing the maximum is returned, we attempt to output it with the `%d` format specifier, which outputs an `int` primitive type value. So `maximum`'s return value is output as an `int` value.

---

[Page 878]

A similar process occurs for the three `double` arguments passed to `maximum` in line 25. Each `double` is

autoboxed as a `Double` object and passed to `maximum`. Again, this is allowed because class `Double` (package `java.lang`) implements the `Comparable< Double >` interface. The `Double` returned by `maximum` is output with the format specifier `%.1f`, which outputs a `double` primitive type value. So `maximum`'s return value is auto-unboxed and output as a `double`. The call to `maximum` in line 27 receives three `Strings`, which are also `Comparable< String >` objects. Note that we intentionally placed the largest value in a different position in each method call (lines 23, 25 and 27) to show that the generic method always finds the maximum value, regardless of its position in the argument list.

When the compiler translates generic method `maximum` into Java bytecodes, it uses erasure (introduced in [Section 18.3](#)) to replace the type parameters with actual types. In [Fig. 18.3](#), all generic types were replaced with type `Object`. Actually, all type parameters are replaced with the upper bound of the type parameter unless specified otherwise, `Object` is the default upper bound. The upper bound of a type parameter is specified in the type parameter section. To indicate the upper bound, follow the type parameter's name with the keyword `extends` and the class or interface name that represents the upper bound. In method `maximum`'s type parameter section ([Fig. 18.5](#)), we specified the upper bound as type `Comparable< T >`. Thus, only `Comparable< T >` objects can be passed as arguments to `maximum`; anything that is not `Comparable< T >` will result in compilation errors. [Figure 18.6](#) simulates the erasure of method `maximum`'s types by showing the method's source code after the type parameter section is removed and type parameter `T` is replaced with the upper bound, `Comparable`, throughout the method declaration. Note that the erasure of `Comparable< T >` is simply `Comparable`.

Figure 18.6. Generic method `maximum` after erasure is performed by the compiler.

```
1 public static Comparable maximum(Comparable x, Comparable y, Comparable z)
2 {
3 Comparable max = x; // assume x is initially the largest
4
5 if (y.compareTo(max) > 0)
6 max = y; // y is the largest so far
7
8 if (z.compareTo(max) > 0)
9 max = z; // z is the largest
10
11 return max; // returns the largest object
12 } // end method maximum
```

After erasure, the compiled version of method `maximum` specifies that it returns type `Comparable`. However, the calling method does not expect to receive a `Comparable`. Rather, the caller expects to receive an object of the same type that was passed to `maximum` as an argument: `Integer`, `Double` or `String` in this example. When the compiler replaces the type parameter information with the upper bound type in the method declaration, it also inserts explicit cast operations in front of each method call to ensure that the returned value is of the type expected by the caller. Thus, the call to `maximum` in line 23 ([Fig. 18.5](#)) is preceded by an `Integer` cast, as in

```
(Integer) maximum(3, 4, 5)
```

the call to `maximum` in line 25 is preceded by a `Double` cast, as in

```
(Double) maximum(6.6, 8.8, 7.7)
```

and the call to `maximum` in line 27 is preceded by a `String` cast, as in

```
(String) maximum("pear", "apple", "orange")
```

In each case, the type of the cast for the return value is inferred from the types of the method arguments in the particular method call because, according to the method declaration, the return type and the argument types match. Note that you cannot use a method that accepts `Objects` because class `Object` provides only an equality comparison. Also note that without generics, programmers are responsible for the casting operation.

[< PREV](#)[NEXT >](#)

## 18.5. Overloading Generic Methods

A generic method may be overloaded. A class can provide two or more generic methods that specify the same method name but different method parameters. For example, generic method `printArray` of [Fig. 18.3](#) could be overloaded with another `printArray` generic method with the additional parameters `lowSubscript` and `highSubscript` to specify the portion of the array to output (see [Exercise 18.5](#)).

A generic method can also be overloaded by non-generic methods that have the same method name and number of parameters. When the compiler encounters a method call, it searches for the method declaration that most precisely matches the method name and the argument types specified in the call. For example, generic method `printArray` of [Fig. 18.3](#) could be overloaded with a version that is specific to `Strings`, which outputs the `Strings` in neat, tabular format (see [Exercise 18.6](#)).

When the compiler encounters a method call, it performs a matching process to determine which method to invoke. The compiler tries to find and use a precise match in which the method names and argument types of the method call match those of a specific method declaration. If there is no such method, the compiler determines whether there is an inexact but applicable matching method.

## 18.6. Generic Classes

The concept of a data structure, such as a stack, can be understood independently of the element type it manipulates. Generic classes provide a means for describing the concept of a stack (or any other class) in a type-independent manner. We can then instantiate type-specific objects of the generic class. This capability provides a wonderful opportunity for software reusability.

---

 [Page 880]

Once you have a generic class, you can use a simple, concise notation to indicate the actual type(s) that should be used in place of the class's type parameter(s). At compilation time, the Java compiler ensures the type safety of your code and uses the erasure techniques described in [Section 18.3](#) and [Section 18.4](#) to enable your client code to interact with the generic class.

One generic `Stack` class, for example, could be the basis for creating many `Stack` classes (e.g., "`Stack of Double`," "`Stack of Integer`," "`Stack of Character`," "`Stack of Employee`," etc.). These classes are known as [parameterized classes](#) or [parameterized types](#) because they accept one or more parameters. Recall that type parameters represent only reference types, which means the `Stack` generic class cannot be instantiated with primitive types. However, we can instantiate a `Stack` that stores objects of Java's type-wrapper classes and allow Java to use autoboxing to convert the primitive values into objects. Autoboxing occurs when a value of a primitive type (e.g., `int`) is pushed onto a `Stack` that contains wrapper-class objects (e.g., `Integer`). Auto-unboxing occurs when an object of the wrapper class is popped off the `Stack` and assigned it to a primitive type variable.

[Figure 18.7](#) presents a generic `Stack` class declaration. A generic class declaration looks like a non-generic class declaration, except that the class name is followed by a type parameter section (line 4). In this case, type parameter `E` represents the element type the `Stack` will manipulate. As with generic methods, the type parameter section of a generic class can have one or more type parameters separated by commas. (You will create a generic class with two type parameters in [Exercise 18.8](#).) Type parameter `E` is used throughout the `Stack` class declaration to represent the element type. [ *Note:* This example implements a `Stack` as an array.]

Figure 18.7. Generic class `Stack` declaration.

(This item is displayed on page 881 in the print version)

```

1 // Fig. 18.7: Stack.java
2 // Generic class Stack.
3
4 public class Stack< E >
5 {
6 private final int size; // number of elements in the stack
7 private int top; // location of the top element
8 private E[] elements; // array that stores stack elements
9
10 // no-argument constructor creates a stack of the default size
11 public Stack()
12 {
13 this(10); // default stack size
14 } // end no-argument Stack constructor
15
16 // constructor creates a stack of the specified number of elements
17 public Stack(int s)
18 {
19 size = s > 0 ? s : 10; // set size of Stack
20 top = -1; // Stack initially empty
21
22 elements = (E[]) new Object[size]; // create array
23 } // end Stack constructor
24
25 // push element onto stack; if successful, return true;
26 // otherwise, throw FullStackException
27 public void push(E pushValue)
28 {
29 if (top == size - 1) // if stack is full
30 throw new FullStackException(String.format(
31 "Stack is full, cannot push %s", pushValue));
32
33 elements[++top] = pushValue; // place pushValue on Stack
34 } // end method push
35
36 // return the top element if not empty; else throw EmptyStackException
37 public E pop()
38 {
39 if (top == -1) // if stack is empty
40 throw new EmptyStackException("Stack is empty, cannot pop");
41
42 return elements[top--]; // remove and return top element of Stack
43 } // end method pop
44 } // end class Stack< E >

```

Class `Stack` declares variable `elements` as an array of type `E` (line 8). This array will store the `Stack`'s elements. We would like to create an array of type `E` to store the elements. However, the generics mechanism does not allow type parameters in array-creation expressions because the type parameter (in this case, `E`) is not available at runtime. To create an array with the appropriate type, line 22 in the one-argument constructor creates the array as an array of type `Object` and casts the reference returned by `new` to type `E[]`. Any object could be stored in an `Object` array, but the compiler's type-checking mechanism ensures that only objects of the array variable's declared type can be assigned to the array via any array-access expression that uses variable `elements`. Yet when this class is compiled using the `-Xlint:unchecked` option, e.g.,

```
javac -Xlint:unchecked Stack.java
```

the compiler issues the following warning message about line 22:

```
Stack.java:22: warning: [unchecked] unchecked cast
found : java.lang.Object[]
required: E[]
 elements = (E[]) new Object[size]; // create array
```

The reason for this message is that the compiler cannot ensure with 100% certainty that an array of type `Object` will never contain objects of types other than `E`. Assume that `E` represents type `Integer`, so that array elements should store `Integer` objects. It is possible to assign variable `elements` to a variable of type `Object[]`, as in

```
Object[] objectArray = elements;
```

---

[Page 881]

Then any object can be placed into the array with an assignment statement like

```
objectArray[0] = "hello";
```

which places a `String` in an array that should contain only `Integer`s, which would lead to runtime problems when the `Stack` is manipulated. As long as you do not perform statements like those shown here, your `Stack` will contain objects of only the correct element type.

---

[Page 882]

Method `push` (lines 2734) first determines whether an attempt is being made to push an element onto a full `Stack`. If so, lines 3031 throw a `FullStackException`. Class `FullStackException` is declared in [Fig. 18.8](#). If the `Stack` is not full, line 33 increments the top counter and places the argument in that location of array `elements`.

Figure 18.8. `FullStackException` class declaration.

```

1 // Fig. 18.8: FullStackException.java
2 // Indicates a stack is full.
3 public class FullStackException extends RuntimeException
4 {
5 // no-argument constructor
6 public FullStackException()
7 {
8 this("Stack is full");
9 } // end no-argument FullStackException constructor
10
11 // one-argument constructor
12 public FullStackException(String exception)
13 {
14 super(exception);
15 } // end one-argument FullStackException constructor
16 } // end class FullStackException

```

Method `pop` (lines 3743) first determines whether an attempt is being made to pop an element from an empty `Stack`. If so, line 40 throws an `EmptyStackException`. Class `EmptyStackException` is declared in [Fig. 18.9](#). Otherwise, line 42 returns the top element of the `Stack`, then postdecrements the `top` counter to indicate the position of the next top element.

Figure 18.9. `EmptyStackException` class declaration.

```

1 // Fig. 18.9: EmptyStackException.java
2 // Indicates a stack is full.
3 public class EmptyStackException extends RuntimeException
4 {
5 // no-argument constructor
6 public EmptyStackException()
7 {
8 this("Stack is empty");
9 } // end no-argument EmptyStackException constructor
10
11 // one-argument constructor
12 public EmptyStackException(String exception)
13 {
14 super(exception);
15 } // end one-argument EmptyStackException constructor
16 } // end class EmptyStackException

```

Classes `FullStackException` ([Fig. 18.8](#)) and `EmptyStackException` ([Fig. 18.9](#)) each provide the conventional no-argument constructor and one-argument constructor of exception classes (as discussed in [Section 13.11](#)). The no-argument constructor sets the default error message, and the one-argument constructor sets a custom exception message.

As with generic methods, when a generic class is compiled, the compiler performs erasure on the class's type parameters and replaces them with their upper bounds. For class `Stack` ([Fig. 18.7](#)), no upper bound is

specified, so the default upper bound, `Object`, is used. The scope of a generic class's type parameter is the entire class. However, type parameters cannot be used in a class's `static` declarations.

Now, let's consider the test application ([Fig. 18.10](#)) that uses the `Stack` generic class. Lines 910 declare variables of type `Stack< Double >` (pronounced "Stack of Double") and `Stack< Integer >` (pronounced "Stack of Integer"). The types `Double` and `Integer` are known as the `Stack`'s **type arguments**. They are used by the compiler to replace the type parameters so that the compiler can perform type checking and insert cast operations as necessary. We'll discuss the cast operations in more detail shortly. Method `testStack` (called from `main`) instantiates objects `doubleStack` of size 5 (line 15) and `integerStack` of size 10 (line 16), then calls methods `testPushDouble` (lines 2544), `testPopDouble` (lines 4767), `testPushInteger` (lines 7089) and `testPopInteger` (lines 92112) to demonstrate the two `Stack`s in this example.

Figure 18.10. Generic class `Stack` test program.

(This item is displayed on pages 883 - 886 in the print version)

```
1 // Fig. 18.10: StackTest.java
2 // Stack generic class test program.
3
4 public class StackTest
5 {
6 private double[] doubleElements = { 1.1, 2.2, 3.3, 4.4, 5.5, 6.6 };
7 private int[] integerElements = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 };

```

Method `testPushDouble` (lines 2544) invokes method `push` to place the `double` values 1.1, 2.2, 3.3, 4.4 and 5.5 stored in array `doubleElements` onto `doubleStack`. The `for` loop terminates when the test program attempts to `push` a sixth value onto `doubleStack` (which is full, because `doubleStack` can store only five

elements). In this case, the method throws a `FullStackException` ([Fig. 18.8](#)) to indicate that the `Stack` is full. Lines 3943 catch this exception and print the stack trace information. The stack trace indicates the exception that occurred and shows that `Stack` method `push` generated the exception at lines 3031 of the file `Stack.java` ([Fig. 18.7](#)). The trace also shows that method `push` was called by `StackTest` method `testPushDouble` at line 36 of `StackTest.java`, that method `testPushDouble` was called from method `testStacks` at line 18 of `StackTest.java` and that method `testStacks` was called from method `main` at line 117 of `StackTest.java`. This information enables you to determine the methods that were on the method-call stack at the time that the exception occurred. Because the program catches the exception, the Java runtime environment considers the exception to have been handled and the program can continue executing. Note that autoboxing occurs in line 36 when the program tries to push a primitive `double` value onto the `doubleStack`, which stores only `Double` objects.

---

[Page 886]

Method `testPopDouble` (lines 4767) invokes `Stack` method `pop` in an infinite `while` loop to remove all the values from the stack. Note in the output that the values indeed `pop` off in last-in-first-out order (this, of course, is the defining characteristic of stacks). The `while` loop (lines 5761) continues until the stack is empty (i.e., until an `EmptyStackException` occurs), which causes the program to proceed to the `catch` block (lines 6266) and handle the exception, so the program can continue executing. When the test program attempts to `pop` a sixth value, the `doubleStack` is empty, so the `pop` throws an `EmptyStackException`. Auto-unboxing occurs in line 58 when the program assigns the `Double` object popped from the stack to a `double` primitive variable. Recall from [Section 18.4](#) that the compiler inserts cast operations to ensure that the proper types are returned from generic methods. After erasure, `Stack` method `pop` returns type `Object`. However, the client code in method `testPopDouble` expects to receive a `double` when method `pop` returns. So the compiler inserts a `Double` cast, as in

```
popValue = (Double) doubleStack.pop();
```

to ensure that a reference of the appropriate type is returned, auto-unboxed and assigned to `popValue`.

---

[Page 887]

Method `testPushInteger` (lines 7089) invokes `Stack` method `push` to place values onto `integerStack` until it is full. Method `testPopInteger` (lines 92112) invokes `Stack` method `pop` to remove values from `integerStack` until it is empty. Once again, note that the values `pop` off in last-in-first-out order. During the erasure process, the compiler recognizes that the client code in method `testPopInteger` expects to receive an `int` when method `pop` returns. So the compiler inserts an `Integer` cast, as in

```
popValue = (Integer) integerStack.pop();
```

to ensure that a reference of the appropriate type is returned, auto-unboxed and assigned to `popValue`.

## Creating Generic Methods to Test Class `Stack< E >`

Note that the code in methods `testPushDouble` and `testPushInteger` is almost identical for pushing values onto a `Stack< Double >` or a `Stack< Integer >`, respectively, and the code in methods `testPopDouble` and `testPopInteger` is almost identical for popping values from a `Stack< Double >` or a `Stack< Integer >`, respectively. This presents another opportunity to use generic methods. [Figure 18.11](#) declares generic method `testPush` (lines 2646) to perform the same tasks as `testPushDouble` and `testPushInteger` in [Fig. 18.10](#) that is, `push` values onto a `Stack< T >`. Similarly, generic method `testPop` (lines 4969) performs the same tasks as `testPopDouble` and `testPopInteger` in [Fig. 18.10](#) that is, `pop` values off a `Stack< T >`. Note that

the output of [Fig. 18.11](#) precisely matches the output of [Fig. 18.10](#).

 at StackTest2.testPop(StackTest2.java:60)  
 at StackTest2.testStacks(StackTest2.java:22)  
 at StackTest2.main(StackTest2.java:74)

The `testStacks` method (lines 1423) creates the `Stack< Double >` (line 16) and `Stack< Integer >` (line 17) objects. Lines 1922 invoke generic methods `testPush` and `testPop` to test the `Stack` objects. Recall that type parameters can represent only reference types. Therefore, to be able to pass arrays `doubleElements` and `integerElements` to generic method `testPush`, the arrays declared in lines 68 must be declared with the wrapper types `Double` and `Integer`. When these arrays are initialized with primitive values, the compiler autoboxes each primitive value.

Generic method `testPush` (lines 2646) uses type parameter `T` (specified at line 26) to represent the data type stored in the `Stack< T >`. The generic method takes three arguments: a `String` that represents the name of the `Stack< T >` object for output purposes, a reference to an object of type `Stack< T >` and an array of type `T` the type of elements that will be pushed onto `Stack< T >`. Note that the compiler enforces consistency between the type of the `Stack` and the elements that will be pushed onto the `Stack` when `push` is invoked, which is the real value of the generic method call. Generic method `testPop` (lines 4969) takes two arguments: a `String` that represents the name of the `Stack< T >` object for output purposes and a reference to an object of type `Stack< T >`.

## 18.7. Raw Types

The test programs for generic class `Stack` in [Section 18.6](#) instantiate `Stacks` with type arguments `Double` and `Integer`. It is also possible to instantiate generic class `Stack` without specifying a type argument, as follows:

```
Stack objectStack = new Stack(5); // no type argument specified
```

In this case, the `objectStack` is said to have a **raw type**, which means that the compiler implicitly uses type `Object` throughout the generic class for each type argument. Thus the preceding statement creates a `Stack` that can store objects of any type. This is important for backwards compatibility with prior versions of Java. For example, the data structures of the Java Collections Framework (see [Chapter 19](#), Collections) all stored references to `Objects`, but are now implemented as generic types.

A raw type `Stack` variable can be assigned a `Stack` that specifies a type argument, such as a `Stack< Double >` object, as follows:

```
Stack rawTypeStack2 = new Stack< Double >(5);
```

because type `Double` is a subclass of `Object`. This assignment is allowed because the elements in a `Stack< Double >` (i.e., `Double` objects) are certainly objectsclass `Double` is an indirect subclass of `Object`.

Similarly, a `Stack` variable that specifies a type argument in its declaration can be assigned a raw type `Stack` object, as in:

```
Stack< Integer > integerStack = new Stack(10);
```

Although this assignment is permitted, it is unsafe because a `Stack` of raw type might store types other than `Integer`. In this case, the compiler issues a warning message which indicates the unsafe assignment.

The test program of [Fig. 18.12](#) uses the notion of raw type. Line 14 instantiates generic class `Stack` with raw type, which indicates that `rawTypeStack1` can hold objects of any type. Line 17 assigns a `Stack< Double >` to variable `rawTypeStack2`, which is declared as a `Stack` of raw type. Line 20 assigns a `Stack` of raw type to `Stack< Integer >` variable, which is legal but causes the compiler to issue a warning message ([Fig. 18.13](#)) indicating a potentially unsafe assignmentagain, this occurs because a `Stack` of raw type might store types other than `Integer`. Also, each of the calls to generic method `testPush` and `testPop` in lines 2225 results in a compiler warning message ([Fig. 18.13](#)). These warnings occur because variables `rawTypeStack1` and `rawTypeStack2` are declared as `Stacks` of raw type, but methods `testPush` and `testPop` each expect a second argument that is a `Stack` with a specific type argument. The warnings indicate that the compiler cannot guarantee that the types manipulated by the stacks are the correct types, because we did not supply a variable declared with a type argument. Methods `testPush` (lines 3151) and `testPop` (lines 5474) are the same as in [Fig. 18.11](#).

Figure 18.12. Raw type test program.

5 warnings

```

[Figure 18.13](#) shows the warning messages generated by the compiler (compiled with the `-Xlint:unchecked` option) when the file `RawTypeTest.java` ([Fig. 18.12](#)) is compiled. The first warning is generated for line 20, which assigned a raw type `Stack` to a `Stack< Integer >` variable the compiler cannot ensure that all objects

in the `Stack` will be `Integer` objects. The second warning is generated for line 22. Because the second method argument is a raw type `Stack` variable, the compiler determines the type argument for method `testPush` from the `Double` array passed as the third argument. In this case, `Double` is the type argument, so the compiler expects a `Stack< Double >` to be passed as the second argument. The warning occurs because the compiler cannot ensure that a raw type `Stack` contains only `Double` objects. The warning at line 24 occurs for the same reason, even though the actual `Stack` that `rawTypeStack2` references is a `Stack< Double >`. The compiler cannot guarantee that the variable will always refer to the same `Stack` object, so it must use the variable's declared type to perform all type checking. Lines 23 and 25 each generate warnings because method `testPop` expects as an argument a `Stack` for which a type argument has been specified. However, in each call to `testPop`, we pass a raw type `Stack` variable. Thus, the compiler indicates a warning because it cannot check the types used in the body of the method.

## 18.8. Wildcards in Methods That Accept Type Parameters

In this section, we introduce a powerful generics concept known as [wildcards](#). For this purpose, we will also introduce a new data structure from package `java.util`. [Chapter 19](#), Collections, discusses the Java Collections Framework, which provides many generic data structures and algorithms that manipulate the elements of those data structures. Perhaps the simplest of these data structures is class `ArrayList` a dynamically resizable, array-like data structure. As part of this discussion, you will learn how to create an `ArrayList`, add elements to it and traverse those elements using an enhanced `for` statement.

---

[Page 893]

Before we introduce wildcards, let's consider an example that helps us motivate their use. Suppose that you would like to implement a generic method `sum` that totals the numbers in a collection, such as an `ArrayList`. You would begin by inserting the numbers in the collection. As you know, generic classes can be used only with class or interface types. So the numbers would be autoboxed as objects of the type-wrapper classes. For example, any `int` value would be autoboxed as an `Integer` object, and any `double` value would be autoboxed as a `Double` object. We'd like to be able to total all the numbers in the `ArrayList` regardless of their type. For this reason, we'll declare the `ArrayList` with the type argument `Number`, which is the superclass of both `Integer` and `Double`. In addition, method `sum` will receive a parameter of type `ArrayList<Number>` and total its elements. [Figure 18.14](#) demonstrates totaling the elements of an `ArrayList` of `Numbers`.

---

[Page 894]

Figure 18.14. Totaling the numbers in an `ArrayList<Number>`.

(This item is displayed on page 895 in the print version)

```
1 // Fig. 18.14: TotalNumbers.java
2 // Summing the elements of an ArrayList.
3 import java.util.ArrayList;
4
5 public class TotalNumbers
6 {
7 public static void main(String args[])
8 {
9 // create, initialize and output ArrayList of Numbers containing
10 // both Integers and Doubles, then display total of the elements
11 Number[] numbers = { 1, 2.4, 3, 4.1 }; // Integers and Doubles
12 ArrayList< Number > numberList = new ArrayList< Number >();
13
14 for (Number element : numbers)
15 numberList.add(element); // place each number in numberList
16
17 System.out.printf("numberList contains: %s\n", numberList);
18 System.out.printf("Total of the elements in numberList: %.1f\n",
19 sum(numberList));
20 } // end main
21
22 // calculate total of ArrayList elements
23 public static double sum(ArrayList< Number > list)
```

```

24 {
25 double total = 0; // initialize total
26
27 // calculate sum
28 for (Number element : list)
29 total += element.doubleValue();
30
31 return total;
32 } // end method sum
33 } // end class TotalNumbers

```

```

numberList contains: [1, 2.4, 3, 4.1]
Total of the elements in numberList: 10.5

```

Line 11 declares and initializes an array of `Numbers`. Because the initializers are primitive values, Java autoboxes each primitive value as an object of its corresponding wrapper type. The `int` values 1 and 3 are autoboxed as `Integer` objects, and the `double` values 2.4 and 4.1 are autoboxed as `Double` objects. Line 12 declares and creates an `ArrayList` object that stores `Numbers` and assigns it to variable `numberList`. Note that we do not have to specify the size of the `ArrayList` because it will grow automatically as we insert objects.

Lines 14-15 traverse array `numbers` and place each element in `numberList`. Method `add` of class `ArrayList` appends an element to the end of the collection. Line 17 outputs the contents of the `ArrayList` as a `String`. This statement implicitly invokes the `ArrayList`'s `toString` method, which returns a string of the form "`[elements]`" in which *elements* is a comma-separated list of the elements' string representations. Lines 18-19 display the sum of the elements that is returned by the call to method `sum` at line 19.

Method `sum` (lines 23-32) receives an `ArrayList` of `Numbers` and calculates the total of the `Numbers` in the collection. The method uses `double` values to perform the calculations and returns the result as a `double`. Line 25 declares local variable `total` and initializes it to 0. Lines 28-29 use the enhanced `for` statement, which is designed to work with both arrays and the collections of the Collections Framework, to total the elements of the `ArrayList`. The `for` statement assigns each `Number` in the `ArrayList` to variable `element`, then uses method `doubleValue` of class `Number` to obtain the `Number`'s underlying primitive value as a `double` value. The result is added to `total`. When the loop terminates, the method returns the `total`.

## Implementing Method `sum` With a Wildcard Type Argument in Its Parameter

Recall that the purpose of method `sum` in [Fig. 18.14](#) was to total any type of `Numbers` stored in an `ArrayList`. We created an `ArrayList` of `Numbers` that contained both `Integer` and `Double` objects. The output of [Fig. 18.14](#) demonstrates that method `sum` worked properly. Given that method `sum` can total the elements of an `ArrayList` of `Numbers`, you might expect that the method would also work for `ArrayLists` that contain elements of only one numeric type, such as `ArrayList< Integer >`. So we modified class `TotalNumbers` to create an `ArrayList` of `Integers` and pass it to method `sum`. When we compile the program, the compiler issues the following error message:

```
sum(java.util.ArrayList<java.lang.Number>) in TotalNumbersErrors
cannot be applied to (java.util.ArrayList<java.lang.Integer>)
```

Although `Number` is the superclass of `Integer`, the compiler does not consider the parameterized type `ArrayList< Number >` to be a supertype of `ArrayList< Integer >`. If it were, then every operation we could perform on `ArrayList< Number >` would also work on an `ArrayList< Integer >`. Consider the fact that you can add a `Double` object to an `ArrayList< Number >` because a `Double` *is* a `Number`, but you cannot add a `Double` object to an `ArrayList< Integer >` because a `Double` *is not* an `Integer`. Thus, the subtype relationship does not hold.

How do we create a more flexible version of method `sum` that can total the elements of any `ArrayList` that contains elements of any subclass of `Number`? This is where [wildcard type arguments](#) are important. Wildcards enable you to specify method parameters, return values, variables or fields, etc. that act as supertypes of parameterized types. In [Fig. 18.15](#), method `sum`'s parameter is declared in line 50 with the type:

```
ArrayList< ? extends Number >
```

Figure 18.15. Wildcard test program.

(This item is displayed on pages 896 - 897 in the print version)

```
1 // Fig. 18.15: WildcardTest.java
2 // Wildcard test program.
3 import java.util.ArrayList;
4
5 public class WildcardTest
6 {
7 public static void main(String args[])
8 {
9 // create, initialize and output ArrayList of Integers, then
10 // display total of the elements
11 Integer[] integers = { 1, 2, 3, 4, 5 };
12 ArrayList< Integer > integerList = new ArrayList< Integer >();
13
14 // insert elements in integerList
15 for (Integer element : integers)
16 integerList.add(element);
17
18 System.out.printf("integerList contains: %s\n", integerList);
19 System.out.printf("Total of the elements in integerList: %.0f\n\n",
20 sum(integerList));
21
22 // create, initialize and output ArrayList of Doubles, then
23 // display total of the elements
24 Double[] doubles = { 1.1, 3.3, 5.5 };
25 ArrayList< Double > doubleList = new ArrayList< Double >();
26
27 // insert elements in doubleList
28 for (Double element : doubles)
29 doubleList.add(element);
30
31 System.out.printf("doubleList contains: %s\n", doubleList);
32 System.out.printf("Total of the elements in doubleList: %.1f\n\n",
```

```

33 sum(doubleList));
34
35 // create, initialize and output ArrayList of Numbers containing
36 // both Integers and Doubles, then display total of the elements
37 Number[] numbers = { 1, 2.4, 3, 4.1 }; // Integers and Doubles
38 ArrayList< Number > numberList = new ArrayList< Number >();
39
40 // insert elements in numberList
41 for (Number element : numbers)
42 numberList.add(element);
43
44 System.out.printf("numberList contains: %s\n", numberList);
45 System.out.printf("Total of the elements in numberList: %.1f\n",
46 sum(numberList));
47 } // end main
48
49 // calculate total of stack elements
50 public static double sum(ArrayList< ? extends Number > list)
51 {
52 double total = 0; // initialize total
53
54 // calculate sum
55 for (Number element : list)
56 total += element.doubleValue();
57
58 return total;
59 } // end method sum
60 } // end class WildcardTest

```

```

integerList contains: [1, 2, 3, 4, 5]
Total of the elements in integerList: 15

doubleList contains: [1.1, 3.3, 5.5]
Total of the elements in doubleList: 9.9

numberList contains: [1, 2.4, 3, 4.1]
Total of the elements in numberList: 10.5

```

A wildcard type argument is denoted by a question mark ( ? ). A question mark by itself represents an "unknown type." In this case, the wildcard extends class `Number`, which means that the wildcard has an upper bound of `Number`. Thus, the unknown type argument must be either `Number` or a subclass of `Number`. With the parameter type shown here, method `sum` can receive an `ArrayList` argument that contains any type of `Number`, such as `ArrayList< Integer >` (line 20), `ArrayList< Double >` (line 33) or `ArrayList< Number >` (line 46).

Lines 1120 create and initialize an `ArrayList< Integer >` called `integerList`, output its elements and total its elements by calling method `sum` (line 20). Lines 2433 perform the same operations for an `ArrayList< Double >` called `doubleList`. Lines 3746 perform the same operations for an `ArrayList< Number >` called `numberList` that contains both `Integers` and `Doubles`.

In method `sum` (lines 5059), although the `ArrayList` argument's element types are not directly known by the method, they are known to be at least of type `Number` because the wildcard was specified with the upper bound `Number`. For this reason, line 56 is allowed because all `Number` objects have a `doubleValue` method.

Although wildcards provide flexibility when passing parameterized types to a method, they also have some disadvantages. Because the wildcard (`?`) in the method's header (line 50) does not specify a type parameter name, you cannot use it as a type name throughout the method's body (i.e., you cannot replace `Number` with `?` in line 55). If the wildcard is specified without an upper bound, then only the methods of type `Object` can be invoked on values of the wildcard type. Also, methods that use wildcards in their parameter's type arguments cannot be used to add elements to a collection referenced by the parameter.

## Common Programming Error 18.4

*Using a wildcard in a method's type parameter section or using a wildcard as an explicit type of a variable in the method body is a syntax error.*

## 18.9. Generics and Inheritance: Notes

Generics can be used with inheritance in several ways:

- A generic class can be derived from a non-generic class. For example, the `Object` class is a direct or indirect superclass of every generic class.
- A generic class can be derived from another generic class. For example, generic class `Stack` (in package `java.util`) is a subclass of generic class `Vector` (in package `java.util`). We discuss these classes in [Chapter 19](#), Collections.
- A non-generic class can be derived from a generic class. For example, non-generic class `Properties` (in package `java.util`) is a subclass of generic class `Hashtable` (in package `java.util`). We also discuss these classes in [Chapter 19](#).
- Finally, a generic method in a subclass can override a generic method in a superclass if both methods have the same signatures.

## 18.10. Wrap-Up

This chapter introduced J2SE 5.0's new generics capability. You learned how to declare generic methods and classes. You learned how J2SE 5.0 achieves backwards compatibility via raw types. You also learned how to use wildcards in a generic method or a generic class. In the next chapter, we demonstrate the interfaces, classes and algorithms of the Java collections framework. As you will see, the collections presented all use the generics capabilities you learned here.

## Summary

- Generic methods enable programmers to specify, with a single method declaration, a set of related methods.
- Generic classes enable programmers to specify, with a single class declaration, a set of related types.
- Generic methods and classes are among Java's most powerful capabilities for software reuse with compile-time type safety.
- Overloaded methods are often used to perform similar operations on different types of data.
- When the compiler encounters a method call, it always attempts to locate a method declaration that has the same method name and parameters that match the argument types in the method call.
- If the operations performed by several overloaded methods are identical for each argument type, the overloaded methods can be more compactly and conveniently coded using a generic method. You can write a single generic method declaration, which can be called with arguments of different data types. Based on the types of the arguments passed to the generic method, the compiler handles each method call appropriately.
- All generic method declarations have a type parameter section delimited by angle brackets (< and >) that precedes the method's return type.
- Each type parameter section contains one or more type parameters (also called formal type parameters) separated by commas.
- A type parameter, also known as type variable, is an identifier that specifies a generic type name. The type parameters can be used as the return type, parameter types and local variable types in a generic method declaration, and act as placeholders for the types of the arguments passed to the generic method, which are known as actual type arguments. Type parameters can represent only reference types.
- The names used for type parameters throughout the method declaration must match those declared in the type parameter section. The name of a type parameter can be declared only once in the type parameter section but can appear more than once in the method's parameter list. Type parameter names need not be unique among different generic methods.
- When the compiler encounters a method call, it first determines the argument types and attempts to locate a method with the same name that specifies parameters that match the argument types. If there is no such method, the compiler determines whether there is an inexact but applicable match.
- The relational operator > cannot be used with reference types. However, it is possible to compare two objects of the same class if that class implements the generic interface `Comparable` (package `java.lang`).

- `Comparable` objects have a `compareTo` method that must return 0 if the objects are equal, -1 if the first object is less than the second or 1 if the first object is greater than the second.
- All the type-wrapper classes for primitive types implement `Comparable`.
- A benefit of implementing interface `Comparable` is that `Comparable` objects can be used with the sorting and searching methods of class `Collections` (package `java.util`).

- When the compiler translates a generic method into Java bytecodes, it removes the type parameter section and replaces the type parameters with actual types. This process is known as erasure. By default each type parameter is replaced with its upper bound. By default, the upper bound is type `Object` unless specified otherwise in the type parameter section.
- When the compiler performs erasure on a method that returns a type variable, it also inserts explicit cast operations in front of each method call to ensure that the returned value is of the type expected by the caller.
- A generic method may be overloaded. A class can provide two or more generic methods that specify the same method name but different method parameters. A generic method can also be overloaded by non-generic methods that have the same method name and number of parameters. When the compiler encounters a method call, it searches for the method declaration that most precisely matches the method name and the argument types specified in the call.
- When the compiler encounters a method call, it performs a matching process to determine which method to call. The compiler tries to find and use a precise match in which the method names and argument types of the method call match those of a specific method declaration. If this fails, the compiler determines whether a generic method is available that provides a precise match of the method name and argument types, and if so, uses that generic method.
- Generic classes provide a means for describing a class in a type-independent manner. We can then instantiate type-specific objects of the generic class.
- A generic class declaration looks like a non-generic class declaration, except that the class name is followed by a type parameter section. As with generic methods, the type parameter section of a generic class can have one or more type parameters separated by commas.
- When a generic class is compiled, the compiler performs erasure on the class's type parameters and replaces them with their upper bounds.
- Type parameters cannot be used in a class's `static` declarations.
- When instantiating an object of a generic class, the types specified in angle brackets after the class name are known as type arguments. They are used by the compiler to replace the type parameters so that the compiler can perform type checking and insert cast operations as necessary.
- It is possible to instantiate a generic class without specifying a type argument. In this case, the new object of the class is said to have a raw type, which means that the compiler implicitly uses type `Object` (or the type parameter's upper bound) throughout the generic class for each type argument.
- The Java Collections Framework provides many generic data structures and algorithms that manipulate the elements of those data structures. Perhaps the simplest of the data structures is class `ArrayList` a dynamically resizable, array-like data structure.
- Class `Number` is the superclass of both `Integer` and `Double`.
- Method `add` of class `ArrayList` appends an element to the end of the collection.
- Method `toString` of class `ArrayList` returns a string of the form "`[ elements ]`" in which *elements* is a comma-separated list of the elements' string representations.
- Method `doubleValue` of class `Number` obtains the `Number`'s underlying primitive value as a `double` value.

- Wildcard type arguments enable you to specify method parameters, return values, variables, etc. that act as supertypes of parameterized types. A wildcard type argument is denoted by the question mark (`?`), which represents an "unknown type." A wildcard can also have an upper bound.
- Because a wildcard (`?`) is not a type parameter name, you cannot use it as a type name throughout a method's body.

- If a wildcard is specified without an upper bound, then only the methods of type `Object` can be invoked on values of the wildcard type.
- Methods that use wildcards as type arguments cannot be used to add elements to a collection referenced by the parameter.
- A generic class can be derived from a non-generic class. For example, `Object` is a direct or indirect superclass of every generic class.
- A generic class can be derived from another generic class.
- A non-generic class can be derived from a generic class.
- A generic method in a subclass can override a generic method in a superclass if both methods have the same signatures.

## Self-Review Exercises

18.1 State whether each of the following is *true* or *false*. If *false*, explain why.

- a. A generic method cannot have the same method name as a non-generic method.
  - b. All generic method declarations have a type parameter section that immediately precedes the method name.
  - c. A generic method can be overloaded by another generic method with the same method name but different method parameters.
  - d. A type parameter can be declared only once in the type parameter section but can appear more than once in the method's parameter list.
  - e. Type parameter names among different generic methods must be unique.
  - f. The scope of a generic class's type parameter is the entire class except its `static` members.
- 

[Page 902]

18.2 Fill in the blanks in each of the following:

- a. \_\_\_\_\_ and \_\_\_\_\_ enable programmers to specify, with a single method declaration, a set of related methods, or with a single class declaration, a set of related types, respectively.
- b. A type parameter section is delimited by \_\_\_\_\_.
- c. The \_\_\_\_\_ of a generic method can be used to specify the types of the arguments to the method, to specify the return type of the method and to declare variables within the method.
- d. The statement "`Stack objectStack = new Stack();`" indicates that `objectStack` stores \_\_\_\_\_.
- e. In a generic class declaration, the class name is followed by a(n) \_\_\_\_\_.
- f. The syntax \_\_\_\_\_ specifies that the upper bound of a wildcard is type `E`.

## Answers to Self-Review Exercises

18.1 a) False. Generic methods and non-generic methods can have same method name. A generic method can overload another generic method with the same method name but different method parameters. A generic method also can be overloaded by providing non-generic methods with the same method name and number of arguments. b) False. All generic method declarations have a type parameter section that immediately precedes the method's return type. c) True. d) True. e) False. Type parameter names among different generic methods need not be unique. f) True.

18.2 a) Generic methods, generic classes. b) angle brackets (< and >). c) type parameters. d) a raw type. e) type parameter section. f) ? `extends E` .

## Exercises

- 18.3 Explain the use of the following notation in a Java program:

```
public class Array< T > { }
```

- 18.4 Write a generic method `selectionSort` based on the sort program of [Fig. 16.6](#) and [Fig. 16.7](#). Write a test program that inputs, sorts and outputs an `Integer` array and a `Float` array. [*Hint*: Use `< T extends Comparable< T > >` in the type parameter section for method `selectionSort`, so that you can use method `compareTo` to compare the objects of two generic types `T`.]
- 18.5 Overload generic method `printArray` of [Fig. 18.3](#) so that it takes two additional integer arguments, `lowSubscript` and `highSubscript`. A call to this method prints only the designated portion of the array. Validate `lowSubscript` and `highSubscript`. If either is out-of-range, or if `highSubscript` is less than or equal to `lowSubscript`, the overloaded `printArray` method should throw an `InvalidSubscriptException`; otherwise, `printArray` should return the number of elements printed. Then modify `main` to exercise both versions of `printArray` on arrays `integerArray`, `doubleArray` and `characterArray`. Test all capabilities of both versions of `printArray`.
- 18.6 Overload generic method `printArray` of [Fig. 18.3](#) with a non-generic version that specifically prints an array of strings in neat, tabular format, as shown in the sample output that follows:

```
Array stringArray contains:
one two three four
five six seven eight
```

- 18.7 Write a simple generic version of method `isEqualTo` that compares its two arguments with the `equals` method and returns `TRUE` if they are equal and `false` otherwise. Use this generic method in a program that calls `isEqualTo` with a variety of built-in types, such as `Object` or `Integer`. What result do you get when you attempt to run this program?
- 18.8 Write a generic class `Pair` which has two type parameters `F` and `S`, each represents the type of the first and second element of the pair respectively. Add `get` and `set` methods for the first and second elements of the pair. [*Hint*: The class header should be `public class Pair< F, S >`.]
- 18.9 Convert classes `TTreeNode` and `tree` from [Fig. 17.17](#) into generic classes. To insert an object in a `tree`, the object must be compared to the objects in existing `treeNodes`. For this reason, classes `treeNode` and `tree` should specify `Comparable< E >` as the upper bound of each class's type parameter. After modifying classes `treeNode` and `tree`, write a test application that creates three `tree` objects one that stores `Integers`, one that stores `Doubles` and one that

stores `Strings`. Insert 10 values into each tree. Then output the preorder, inorder and postorder traversals for each `tree`.

- 18.10 Modify your test program from [Exercise 18.9](#) to use a generic method named `testTree` to test the three `TRee` objects. The method should be called three times once for each `TRee` object.
- 18.11 How can generic methods be overloaded?
- 18.12 The compiler performs a matching process to determine which method to call when a method is invoked. Under what circumstances does an attempt to make a match result in a compile-time error?
- 18.13 Explain why a Java program might use the statement

```
ArrayList< Employee > workerList = new ArrayList< Employee >();
```

# Chapter 19. Collections

*I think this is the most extraordinary collection of talent, of human knowledge, that has ever been gathered together at the White House with the possible exception of when Thomas Jefferson dined alone.*

John F. Kennedy

*The shapes a bright container can contain!*

*Journey over all the universe in a map.*

Miguel de Cervantes

*Not by age but by capacity is wisdom acquired.*

Titus Maccius Plautus

*It is a riddle wrapped in a mystery inside an enigma.*

Winston Churchill

## OBJECTIVES

In this chapter you will learn:

- What collections are.
- To use class `Arrays` for array manipulations.
- To use the collections framework (prepackaged data structure) implementations.
- To use collections framework algorithms to manipulate (such as `search`, `sort` and `fill`) collections.
- To use the collections framework interfaces to program with collections polymorphically.
- To use iterators to "walk through" a collection.
- To use persistent hash tables manipulated with objects of class `Properties`.
- To use synchronization and modifiability wrappers.

## Outline

[19.1](#) Introduction

## 19.1. Introduction

In [Chapter 17](#), we discussed how to create and manipulate data structures. The discussion was "low level" in the sense that we painstakingly created each element of each data structure dynamically and modified the data structures by directly manipulating their elements and the references to their elements. In this chapter, we consider the Java [collections framework](#), which contains prepackaged data structures, interfaces and algorithms for manipulating those data structures. Some examples of collections are the cards you hold in a card game, your favorite songs stored in your computer, the members of a sports team and the real-estate records in your local registry of deeds (which map book numbers and page numbers to property owners). In this chapter, we also discuss how generics (see [Chapter 18](#)) are used in the Java collections framework.

With collections, programmers use existing data structures, without concern for how they are implemented. This is a marvelous example of code reuse. Programmers can code faster and can expect excellent performance, maximizing execution speed and minimizing memory consumption. In this chapter, we discuss the collections framework interfaces that list the capabilities of each collection type, the implementation classes, the algorithms that process the collections, and the so-called [iterators](#) and enhanced `for` statement syntax that "walk through" collections. This chapter provides an introduction to the collections framework. For complete details, visit [java.sun.com/j2se/5.0/docs/guide/collections](http://java.sun.com/j2se/5.0/docs/guide/collections).

The Java collections framework provides ready-to-go, reusable componentry you do not need to write your own collection classes, but you can if you wish to. The collections are standardized so that applications can share them easily without concern with for details of their implementation. The collections framework encourages further reusability. As new data structures and algorithms are developed that fit this framework, a large base of programmers will already be familiar with the interfaces and algorithms implemented by those data structures.

## 19.2. Collections Overview

A [collection](#) is a data structure that actually, an object that can hold references to other objects. Usually, collections contain references to objects that are all of the same type. The collections framework interfaces declare the operations to be performed generically on various types of collections. [Figure 19.1](#) lists some of the interfaces of the collections framework. Several implementations of these interfaces are provided within the framework. Programmers may also provide implementations specific to their own requirements.

Figure 19.1. Some collection framework interfaces.

| Interface                  | Description                                                                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Collection</a> | The root interface in the collections hierarchy from which interfaces <a href="#">Set</a> , <a href="#">Queue</a> and <a href="#">List</a> are derived. |
| <a href="#">Set</a>        | A collection that does not contain duplicates.                                                                                                          |
| <a href="#">List</a>       | An ordered collection that can contain duplicate elements.                                                                                              |
| <a href="#">Map</a>        | Associates keys to values and cannot contain duplicate keys.                                                                                            |
| <a href="#">Queue</a>      | Typically a first-in, first-out collection that models a waiting line; other orders can be specified.                                                   |

The collections framework provides high-performance, high-quality implementations of common data structures and enables software reuse. These features minimize the amount of coding programmers need to do to create and manipulate collections. The classes and interfaces of the collections framework are members of package `java.util`. In the next section, we begin our discussion by examining the collections framework capabilities for array manipulation.

In earlier versions of Java, the classes in the collections framework stored and manipulated [Object](#) references. Thus, you could store any object in a collection. One inconvenient aspect of storing [Object](#) references occurs when retrieving them from a collection. A program normally has the need to process specific types of objects. As a result, the [Object](#) references obtained from a collection typically need to be cast to an appropriate type to allow the program to process the objects correctly.

In J2SE 5.0, the collections framework has been enhanced with the generics capabilities we introduced in [Chapter 18](#). This means that you can specify the exact type that will be stored in a collection. You also receive the benefits of compile-time type checking; the compiler ensures that you are using appropriate types with your collection and, if not, issues compile-time error messages. Also, once you specify the type stored in a collection, any reference you retrieve from the collection will have the specified type. This eliminates the need for explicit type casts that can throw [ClassCastException](#)s if the referenced object is not of the appropriate type. Programs that were implemented with prior Java versions and that use collections can compile properly because the compiler automatically uses raw types when it encounters collections for which type arguments were not specified.

## 19.3. Class **Arrays**

Class **Arrays** provides **static** methods for manipulating arrays. In [Chapter 7](#), our discussion of array manipulation was low level in the sense that we wrote the actual code to sort and search arrays. Class **Arrays** provides high-level methods, such as **sort** for sorting an array, **binarySearch** for searching a sorted array, **equals** for comparing arrays and **fill** for placing values into an array. These methods are overloaded for primitive-type arrays and **Object** arrays. In addition, methods **sort** and **binarySearch** are overloaded with generic versions that allow programmers to sort and search arrays containing objects of any type. [Figure 19.2](#) demonstrates methods **fill**, **sort**, **binarySearch** and **equals**. Method **main** (lines 6585) creates a **UsingArrays** object and invokes its methods.

Figure 19.2. **Arrays** class methods.

(This item is displayed on pages 908 - 909 in the print version)

```

1 // Fig. 19.2: UsingArrays.java
2 // Using Java arrays.
3 import java.util.Arrays;
4
5 public class UsingArrays
6 {
7 private int intArray[] = { 1, 2, 3, 4, 5, 6 };
8 private double doubleArray[] = { 8.4, 9.3, 0.2, 7.9, 3.4 };
9 private int filledIntArray[], intArrayCopy[];
10
11 // constructor initializes arrays
12 public UsingArrays()
13 {
14 filledIntArray = new int [10]; // create int array with 10 elements
15 intArrayCopy = new int [intArray.length];
16
17 Arrays.fill(filledIntArray, 7); // fill with 7s
18 Arrays.sort(doubleArray); // sort doubleArray ascending
19
20 // copy array intArray into array intArrayCopy
21 System.arraycopy(intArray, 0, intArrayCopy,
22 0, intArray.length);
23 } // end UsingArrays constructor
24
25 // output values in each array
26 public void printArrays()
27 {
28 System.out.print("doubleArray: ");
29 for (double doubleValue : doubleArray)
30 System.out.printf("%.1f ", doubleValue);
31
32 System.out.print("\nintArray: ");
33 for (int intValue : intArray)
34 System.out.printf("%d ", intValue);
35
36 System.out.print("\nfilledIntArray: ");
37 for (int intValue : filledIntArray)

```

```
38 System.out.printf("%d ", intValue);
39
40 System.out.print("\nIntArrayCopy: ");
41 for (int intValue : intArrayCopy)
42 System.out.printf("%d ", intValue);
43
44 System.out.println("\n");
45 } // end method printArrays
46
47 // find value in array intArray
48 public int searchForInt(int value)
49 {
50 return Arrays.binarySearch(intArray, value);
51 } // end method searchForInt
52
53 // compare array contents
54 public void printEquality()
55 {
56 boolean b = Arrays.equals(intArray, intArrayCopy);
57 System.out.printf("IntArray %s intArrayCopy\n",
58 (b ? "==" : "!="));
59
60 b = Arrays.equals(intArray, filledIntArray);
61 System.out.printf("IntArray %s filledIntArray\n",
62 (b ? "==" : "!="));
63 } // end method printEquality
64
65 public static void main(String args[])
66 {
67 UsingArrays usingArrays = new UsingArrays();
68
69 usingArrays.printArrays();
70 usingArrays.printEquality();
71
72 int location = usingArrays.searchForInt(5);
73 if (location >= 0)
74 System.out.printf(
75 "Found 5 at element %d in intArray\n", location);
76 else
77 System.out.println("5 not found in intArray");
78
79 location = usingArrays.searchForInt(8763);
80 if (location >= 0)
81 System.out.printf(
82 "Found 8763 at element %d in intArray\n", location);
83 else
84 System.out.println("8763 not found in intArray");
85 } // end main
86 } // end class UsingArrays
```

```
doubleArray: 0.2 3.4 7.9 8.4 9.3
intArray: 1 2 3 4 5 6
filledIntArray: 7 7 7 7 7 7 7 7 7 7
intArrayCopy: 1 2 3 4 5 6

intArray == intArrayCopy
intArray != filledIntArray
Found 5 at element 4 in intArray
8763 not found in intArray
```

Line 17 calls `static` method `fill` of class `Arrays` to populate all 10 elements of `filledIntArray` with 7s. Overloaded versions of `fill` allow the programmer to populate a specific range of elements with the same value.

Line 18 sorts the elements of array `doubleArray`. The `static` method `sort` of class `Arrays` orders the array's elements in ascending order by default. We discuss how to sort in descending order later in the chapter. Overloaded versions of `sort` allow the programmer to sort a specific range of elements.

Lines 21-22 copy array `intArray` into array `intArrayCopy`. The first argument (`intArray`) passed to `System` method `arraycopy` is the array from which elements are to be copied. The second argument (0) is the index that specifies the starting point in the range of elements to copy from the array. This value can be any valid array index. The third argument (`intArrayCopy`) specifies the destination array that will store the copy. The fourth argument (0) specifies the index in the destination array where the first copied element should be stored. The last argument specifies the number of elements to copy from the array in the first argument. In this case, we copy all the elements in the array.

Line 50 calls `static` method `binarySearch` of class `Arrays` to perform a binary search on `intArray`, using `value` as the key. If `value` is found, `binarySearch` returns the index of the element; otherwise, `binarySearch` returns a negative value. The negative value returned is based on the search key's `insertion point`—the index where the key would be inserted in the array if we were performing an insert operation. After `binarySearch` determines the insertion point, it changes its sign to negative and subtracts 1 to obtain the return value. For example, in [Fig. 19.2](#), the insertion point for the value 8763 is the element with index 6 in the array. Method `binarySearch` changes the insertion point to 6, subtracts 1 from it and returns the value 7. Subtracting 1 from the insertion point guarantees that method `binarySearch` returns positive values ( $\geq 0$ ) if and only if the key is found. This return value is useful for inserting elements in a sorted array. [Chapter 16](#), [Searching and Sorting](#), discusses binary searching in detail.

## Common Programming Error 19.1

*Passing an unsorted array to `binarySearch` is a logic error—the value returned is undefined.*

Lines 56 and 60 call `static` method `equals` of class `Arrays` to determine whether the elements of two arrays are equivalent. If the arrays contain the same elements in the same order, the method returns `true`; otherwise, it returns `false`. The equality of each element is compared using `Object` method `equals`. Many

classes override method `equals` to perform the comparisons in a manner specific to those classes. For example, class `String` declares `equals` to compare the individual characters in the two `Strings` being compared. If method `equals` is not overridden, the original version of method `equals` inherited from class `Object` is used.

## 19.4. Interface **Collection** and Class **Collections**

Interface **Collection** is the root interface in the collection hierarchy from which interfaces **Set**, **Queue** and **List** are derived. Interface **Set** defines a collection that does not contain duplicates. Interface **Queue** defines a collection that represents a waiting line typically, insertions are made at the back of a queue and deletions are made from the front, though other orders can be specified. We discuss **Queue** and **Set** in [Section 19.8](#) and [Section 19.9](#), respectively. Interface **Collection** contains **bulk operations** (i.e., operations performed on an entire collection) for adding, clearing, comparing and retaining objects (or elements) in a collection. A **Collection** can also be converted to an array. In addition, interface **Collection** provides a method that returns an **Iterator** object, which allows a program to walk through the collection and remove elements from the collection during the iteration. We discuss class **Iterator** in [Section 19.5.1](#). Other methods of interface **Collection** enable a program to determine a collection's size and whether a collection is empty.

### Software Engineering Observation 19.1

***Collection** is used commonly as a method parameter type to allow polymorphic processing of all objects that implement interface **Collection**.*

### Software Engineering Observation 19.2

*Most collection implementations provide a constructor that takes a **Collection** argument, thereby allowing a new collection to be constructed containing the elements of the specified collection.*

Class **Collections** provides **static** methods that manipulate collections polymorphically. These methods implement algorithms for searching, sorting and so on. [Chapter 16](#), Searching and Sorting, discussed and implemented various searching and sorting algorithms. [Section 19.6](#) discusses more about the algorithms that are available in class **Collections**. We also cover the **wrapper methods** of class **Collections** that enable you to treat a collection as a **synchronized collection** ([Section 19.12](#)) or an **unmodifiable collection** ([Section 19.13](#)). Unmodifiable collections are useful when a client of a class needs to view the elements of a collection, but should not be allowed to modify the collection by adding and removing elements. Synchronized collections are for use with a powerful capability called multithreading (discussed in [Chapter 23](#)). Multithreading enables programs to perform operations in parallel. When two or more threads of a program share a collection, there is the potential for problems to occur. As a brief analogy, consider a traffic intersection. We cannot allow all cars access to one intersection at the same time if we did, accidents would occur. For this reason, traffic lights are provided at intersections to control access to the intersection. Similarly, we can synchronize access to a collection to ensure that only one thread manipulates the collection at a time. The synchronization wrapper methods of class **collection** return synchronized versions of collections that can be shared among threads in a program.

## 19.5. Lists

A **List** (sometimes called a **sequence**) is an ordered **Collection** that can contain duplicate elements. Like array indices, **List** indices are zero based (i.e., the first element's index is zero). In addition to the methods inherited from **Collection**, **List** provides methods for manipulating elements via their indices, manipulating a specified range of elements, searching for elements and getting a **ListIterator** to access the elements.

Interface **List** is implemented by several classes, including classes **ArrayList**, **LinkedList** and **Vector**. Autoboxing occurs when you add primitive-type values to objects of these classes, because they store only references to objects. Class **ArrayList** and **Vector** are resizable-array implementations of **List**. Class **LinkedList** is a linked-list implementation of interface **List**.

Class **ArrayList**'s behavior and capabilities are similar to those of class **Vector**. The primary difference between **Vector** and **ArrayList** is that objects of class **Vector** are synchronized by default, whereas objects of class **ArrayList** are not. Also, class **Vector** is from Java 1.0, before the collections framework was added to Java. As such, **Vector** has several methods that are not part of interface **List** and are not implemented in class **ArrayList**, but perform identical tasks. For example, **Vector** methods **addElement** and **add** both append an element to a **Vector**, but only method **add** is specified in interface **List** and implemented by **ArrayList**. Unsynchronized collections provide better performance than synchronized ones. For this reason, **ArrayList** is typically preferred over **Vector** in programs that do not share a collection among threads.

### Performance Tip 19.1

***ArrayLists** behave like **Vectors** without synchronization and therefore execute faster than **Vectors** because **ArrayLists** do not have the overhead of thread synchronization.*

### Software Engineering Observation 19.3

***LinkedLists** can be used to create stacks, queues, trees and deques (double-ended queues, pronounced "decks"). The collections framework provides implementations of some of these data structures.*

The following three subsections demonstrate the **List** and **Collection** capabilities with several examples. [Section 19.5.1](#) focuses on removing elements from an **ArrayList** with an **Iterator**. [Section 19.5.2](#) focuses on **ListIterator** and several **List**- and **LinkedList**-specific methods. [Section 19.5.3](#) introduces more **List** methods and several **Vector**-specific methods.

#### 19.5.1. **ArrayList** and **Iterator**

Figure 19.3 uses an `ArrayList` to demonstrate several `Collection` interface capabilities. The program places two `Color` arrays in `ArrayLists` and uses an `Iterator` to remove elements in the second `ArrayList` collection from the first `ArrayList` collection.

Figure 19.3. `Collection` interface demonstrated via an `ArrayList` object.

(This item is displayed on pages 912 - 913 in the print version)

```
1 // Fig. 19.3: CollectionTest.java
2 // Using the Collection interface.
3 import java.util.List;
4 import java.util.ArrayList;
5 import java.util.Collection;
6 import java.util.Iterator;
7
8 public class CollectionTest
9 {
10 private static final String[] colors =
11 { "MAGENTA", "RED", "WHITE", "BLUE", "CYAN" };
12 private static final String[] removeColors =
13 { "RED", "WHITE", "BLUE" };
14
15 // create ArrayList, add Colors to it and manipulate it
16 public CollectionTest()
17 {
18 List< String > list = new ArrayList< String >();
19 List< String > removeList = new ArrayList< String >();
20
21 // add elements in colors array to list
22 for (String color : colors)
23 list.add(color);
24
25 // add elements in removeColors to removeList
26 for (String color : removeColors)
27 removeList.add(color);
28
29 System.out.println("ArrayList: ");
30
31 // output list contents
32 for (int count = 0; count < list.size(); count++)
33 System.out.printf("%s ", list.get(count));
34
35 // remove colors contained in removeList
36 removeColors(list, removeList);
37
38 System.out.println("\n\nArrayList after calling removeColors: ");
39
40 // output list contents
41 for (String color : list)
42 System.out.printf("%s ", color);
43 } // end CollectionTest constructor
44
45 // remove colors specified in collection2 from collection1
46 private void removeColors(
47 Collection< String > collection1, Collection< String > collection2)
48 {
49 // get iterator
50 Iterator< String > iterator = collection1.iterator();
```

```

51
52 // loop while collection has items
53 while (iterator.hasNext())
54
55 if (collection2.contains(iterator.next()))
56 iterator.remove(); // remove current Color
57 } // end method removeColors
58
59 public static void main(String args[])
60 {
61 new CollectionTest();
62 } // end main
63 } // end class CollectionTest

```

```

ArrayList:
MAGENTA RED WHITE BLUE CYAN

ArrayList after calling removeColors:
MAGENTA CYAN

```

Lines 1013 declare and initialize two `String` array variables, which are declared `final`, so they always refer to these arrays. Recall that it is good programming practice to declare constants with keywords `static` and `final`. Lines 1819 create `ArrayList` objects and assign their references to variables `list` and `removeList`, respectively. These two lists store `String` objects. Note that `ArrayList` is a generic class in J2SE 5.0, so we are able to specify a type argument (`String` in this case) to indicate the type of the elements in each list. Both `list` and `removeList` are collections of `Strings`. Lines 2223 populate `list` with `Strings` stored in array `colors`, and lines 2627 populate `removeList` with `Strings` stored in array `removeColors` using `List` method `add`. Lines 3233 output each element of `list`. Line 32 calls `List` method `size` to get the number of `ArrayList` elements. Line 33 uses `List` method `get` to retrieve individual element values. Lines 3233 could have used the enhanced `for` statement. Line 36 calls method `removeColors` (lines 4657), passing `list` and `removeList` as arguments. Method `removeColors` deletes `Strings` specified in `removeList` from the `list` collection. Lines 4142 print `list`'s elements after `removeColors` removes the `String` objects specified in `removeList` from the `list`.

---

[Page 912]

---

[Page 913]

Method `removeColors` declares two `Collection` parameters (line 47) that allow any `Collections` containing strings to be passed as arguments to this method. The method accesses the elements of the first `Collection` (`collection1`) via an `Iterator`. Line 50 calls `Collection` method `iterator` to get an `Iterator` for the `Collection`. Note that interfaces `Collection` and `Iterator` are generic types. The loop-continuation condition (line 53) calls `Iterator` method `hasNext` to determine whether the `Collection` contains more elements. Method `hasNext` returns `TRUE` if another element exists and `false` otherwise.

The `if` condition in line 55 calls `Iterator` method `next` to obtain a reference to the next element, then uses method `contains` of the second `Collection` (`collection2`) to determine whether `collection2` contains the element returned by `next`. If so, line 56 calls `Iterator` method `remove` to remove the element from the `Collection` `collection1`.

## Common Programming Error 19.2

*If a collection is modified by one of its methods after an iterator is created for that collection, the iterator immediately becomes invalid and any operations performed with the iterator after this point throw `ConcurrentModificationExceptions`. For this reason, iterators are said to be "fail fast."*

[Page 914]

### 19.5.2. LinkedList

Figure 19.4 demonstrates operations on `LinkedLists`. The program creates two `LinkedLists` that contain `Strings`. The elements of one `List` are added to the other. Then all the `Strings` are converted to uppercase, and a range of elements is deleted.

Figure 19.4. `Lists` and `ListIterators`.

(This item is displayed on pages 914 - 915 in the print version)

```
1 // Fig. 19.4: ListTest.java
2 // Using LinkLists.
3 import java.util.List;
4 import java.util.LinkedList;
5 import java.util.ListIterator;
6
7 public class ListTest
8 {
9 private static final String colors[] = { "black", "yellow",
10 "green", "blue", "violet", "silver" };
11 private static final String colors2[] = { "gold", "white",
12 "brown", "blue", "gray", "silver" };
13
14 // set up and manipulate LinkedList objects
15 public ListTest()
16 {
17 List< String > list1 = new LinkedList< String >();
18 List< String > list2 = new LinkedList< String >();
19
20 // add elements to list link
21 for (String color : colors)
22 list1.add(color);
23
24 // add elements to list link2
25 for (String color : colors2)

[Page 916]

Lines 1718 create `LinkedLists list1` and `list2` of type `String`. Note that `LinkedList` is a generic class that has one type parameter for which we specify the type argument `String` in this example. Lines 2126 call `List` method `add` to append elements from arrays `colors` and `colors2` to the end of `list1` and `list2`, respectively.

Line 28 calls `List` method `addAll` to append all elements of `list2` to the end of `list1`. Line 29 sets `list2` to `null`, so the `LinkedList` to which `list2` referred can be garbage collected. Line 30 calls method `printList` (lines 4250) to output list `list1`'s contents. Line 32 calls method `convertToUppercaseStrings` (lines 5362) to convert each `String` element to uppercase, then line 33 calls `printList` again to display the modified `Strings`. Line 36 calls method `removeItems` (lines 6568) to remove the elements starting at index 4 up to, but not including, index 7 of the list. Line 38 calls method `printReversedList` (lines 7180) to print the list in reverse order.

Method `convertToUppercaseStrings` (lines 5362) changes lowercase `String` elements in its `List` argument to uppercase `Strings`. Line 55 calls `List` method `listIterator` to get a `bidirectional iterator` (i.e., an iterator that can traverse a `List` backward or forward) for the `List`. Note that `ListIterator` is a generic class. In this example, the `ListIterator` contains `String` objects, because method `listIterator` is called on a `List` of `Strings`. The `while` condition (line 57) calls method `hasNext` to determine whether the `List` contains another element. Line 59 gets the next `String` in the `List`. Line 60 calls `String` method `toUpperCase` to get an uppercase version of the `String` and calls `ListIterator` method `set` to replace the current `String` to which `iterator` refers with the `String` returned by method `toUpperCase`. Like method `toUpperCase`, `String` method `toLowerCase` returns a lowercase version of the `String`.

Method `removeItems` (lines 6568) removes a range of items from the list. Line 67 calls `List` method `subList` to obtain a portion of the `List` (called a `sublist`). The sublist is simply another view into the `List` on which `subList` is called. Method `subList` takes two arguments: the beginning and the ending index for the sublist. The ending index is not part of the range of the sublist. In this example, we pass (in line 36) 4 for the beginning index and 7 for the ending index to `subList`. The sublist returned is the set of elements with indices 4 through 6. Next, the program calls `List` method `clear` on the sublist to remove the elements of the sublist from the `List`. Any changes made to a sublist are also made to the original `List`.

Method `printReversedList` (lines 7180) prints the list backward. Line 73 calls `List` method `listIterator` with one argument that specifies the starting position (in our case, the last element in the list) to get a `bidirectional iterator` for the list. `List` method `size` returns the number of items in the `List`. The `while` condition (line 78) calls method `hasPrevious` to determine whether there are more elements while traversing the list backward. Line 79 gets the previous element from the list and outputs it to the standard output stream.

An important feature of the collections framework is the ability to manipulate the elements of one collection type (such as a set) through a different collection type (such as a list), regardless of the collection's internal implementation. The set of `public` methods through which collections are manipulated is called a `view`.

Class `Arrays` provides `static` method `asList` to view an array as a `List` collection (which encapsulates behavior similar to that of the linked lists created in [Chapter 17](#)). A `List` view allows the programmer to manipulate the array as if it were a list. This is useful for adding the elements in an array to a collection (e.g., a `LinkedList`) and for sorting array elements. The next example demonstrates how to create a `LinkedList` with a `List` view of an array, because we cannot pass the array to a `LinkedList` constructor. Sorting array elements with a `List` view is demonstrated in [Fig. 19.9](#). Any modifications made through the `List` view change the array, and any modifications made to the array change the `List` view. The only operation permitted on the view returned by `asList` is `set`, which changes the value of the view and the backing array. Any other attempts to change the view (such as adding or removing elements) result in an `UnsupportedOperationException`.

---

[Page 917]

[Figure 19.5](#) uses method `asList` to view an array as a `List` collection and uses method `toArray` of a `List` to get an array from a `LinkedList` collection. The program calls method `asList` to create a `List` view of an array, which is then used for creating a `LinkedList` object, adds a series of strings to a `LinkedList` and calls method `toArray` to obtain an array containing references to the strings. Notice that the instantiation of `LinkedList` (line 13) indicates that `LinkedList` is a generic class that accepts one type argument `String`, in this example.

Figure 19.5. `List` method `toArray`.

(This item is displayed on pages 917 - 918 in the print version)

```
1 // Fig. 19.5: UsingToArray.java
2 // Using method toArray.
3 import java.util.LinkedList;
4 import java.util.Arrays;
5
6 public class UsingToArray
7 {
8 // constructor creates LinkedList, adds elements and converts to array
9 public UsingToArray()
10 {
11 String colors[] = { "black", "blue", "yellow" };
12
13 LinkedList< String > links =
14 new LinkedList< String >(Arrays.asList(colors));
15
16 links.addLast("red"); // add as last item
17 links.add("pink"); // add to the end
18 links.add(3, "green"); // add at 3rd index
19 links.addFirst("cyan"); // add as first item
20
21 // get LinkedList elements as an array
22 colors = links.toArray(new String[links.size()]);
23
24 System.out.println("colors: ");
25
26 for (String color : colors)
27 System.out.println(color);
28 } // end UsingToArray constructor
29
30 public static void main(String args[])
31 {
32 new UsingToArray();
```

```
33 } // end main
34 } // end class UsingToArray
```

```
colors:
cyan
black
blue
yellow
green
red
pink
```

[Page 918]

Lines 1314 construct a `LinkedList` of `Strings` containing the elements of array `colors` and assigns the `LinkedList` reference to `links`. Note the use of `Arrays` method `asList` to return a view of the array as a `List`, then initialize the `LinkedList` with the `List`. Line 16 calls `LinkedList` method `addLast` to add "red" to the end of `links`. Lines 1718 call `LinkedList` method `add` to add "pink" as the last element and "green" as the element at index 3 (i.e., the fourth element). Note that method `addLast` (line 16) is identical in function to method `add` (line 17). Line 19 calls `LinkedList` method `addFirst` to add "cyan" as the new first item in the `LinkedList`. The `add` operations are permitted because they operate on the `LinkedList` object, not the view returned by `asList`. [Note: When "cyan" is added as the first element, "green" becomes the fifth element in the `LinkedList`.]

Line 22 calls `List` method `toArray` to get a `String` array from `links`. The array is a copy of the list's elements; modifying the contents of the array does not modify the list. The array passed to method `toArray` is of the same type that you would like method `toArray` to return. If the number of elements in the array is greater than or equal to the number of elements in the `LinkedList`, `toArray` copies the list's elements into its array argument and returns that array. If the `LinkedList` has more elements than the number of elements in the array passed to `toArray`, `toArray` allocates a new array of the same type it receives as an argument, copies the list's elements into the new array and returns the new array.

## Common Programming Error 19.3

*Passing an array that contains data to `toArray` can cause logic errors. If the number of elements in the array is smaller than the number of elements in the list on which `toArray` is called, a new array is allocated to store the list's elements without preserving the array argument's elements. If the number of elements in the array is greater than the number of elements in the list, the elements of the array (starting at index zero) are overwritten with the list's elements. Array elements that are not overwritten retain their values.*

### 19.5.3. Vector

Like `ArrayList`, class `Vector` provides the capabilities of array-like data structures that can resize

themselves dynamically. Recall that class `ArrayList`'s behavior and capabilities are similar to those of class `Vector`, except that `ArrayLists` do not provide synchronization by default. We cover class `Vector` here primarily because it is the superclass of class `Stack`, which is presented in [Section 19.7](#).

At any time, a `Vector` contains a number of elements that is less than or equal to its `capacity`. The capacity is the space that has been reserved for the `Vector`'s elements. If a `Vector` requires additional capacity, it grows by a `capacity increment` that you specify or by a default capacity increment. If you do not specify a capacity increment or specify one that is less than or equal to zero, the system will double the size of a `Vector` each time additional capacity is needed.

---

[Page 919]

## Performance Tip 19.2

*Inserting an element into a `Vector` whose current size is less than its capacity is a relatively fast operation.*

## Performance Tip 19.3

*Inserting an element into a `Vector` that needs to grow larger to accommodate the new element is a relatively slow operation.*

## Performance Tip 19.4

*The default capacity increment doubles the size of the `Vector`. This may seem a waste of storage, but it is actually an efficient way for many `Vectors` to grow quickly to be "about the right size." This operation is much more efficient than growing the `Vector` each time by only as much space as it takes to hold a single element. The disadvantage is that the `Vector` might occupy more space than it requires. This is a classic example of the spacetime trade-off.*

## Performance Tip 19.5

*If storage is at a premium, use `Vector` method `trimToSize` to trim a `Vector`'s capacity to the `Vector`'s exact size. This operation optimizes a `Vector`'s use of storage. However, adding another element to the `Vector` will force the `Vector` to grow dynamically (again, a relatively slow operation) trimming leaves no room for growth.*

Figure 19.6 demonstrates class `Vector` and several of its methods. For complete information on class `Vector`, please visit [java.sun.com/j2se/5.0/docs/api/java/util/Vector.html](http://java.sun.com/j2se/5.0/docs/api/java/util/Vector.html).

21 // output the first and last elements
22 try
23 {
24 System.out.printf("First element: %s\n", vector.firstElement());
25 System.out.printf("Last element: %s\n", vector.lastElement());
26 } // end try
27 // catch exception if vector is empty
28 catch (NoSuchElementException exception)
29 {
30 exception.printStackTrace();
31 } // end catch
32
33 // does vector contain "red"?
34 if (vector.contains("red"))
35 System.out.printf("\n\"red\" found at index %d\n\n",
36 vector.indexOf("red"));
37 else
38 System.out.println("\n\"red\" not found\n");
39
40 vector.remove("red"); // remove the string "red"
41 System.out.println("\"red\" has been removed");
42 printVector(vector); // print vector
43
44 // does vector contain "red" after remove operation?
45 if (vector.contains("red"))
46 System.out.printf(
47 "\"red\" found at index %d\n", vector.indexOf("red"));
```

```

48 else
49 System.out.println("\"red\" not found");
50
51 // print the size and capacity of vector
52 System.out.printf("\nSize: %d\nCapacity: %d\n", vector.size(),
53 vector.capacity());
54 } // end Vector constructor
55
56 private void printVector(Vector< String > vectorToOutput)
57 {
58 if (vectorToOutput.isEmpty())
59 System.out.print("vector is empty"); // vectorToOutput is empty
60 else // iterate through the elements
61 {
62 System.out.print("vector contains: ");
63
64 // output elements
65 for (String element : vectorToOutput)
66 System.out.printf("%s ", element);
67 } // end else
68
69 System.out.println("\n");
70 } // end method printVector
71
72 public static void main(String args[])
73 {
74 new VectorTest(); // create object and call its constructor
75 } // end main
76 } // end class VectorTest

```

```

vector is empty

vector contains: red white blue

First element: red
Last element: blue

"red" found at index 0

"red" has been removed
vector contains: white blue

"red" not found

Size: 2
Capacity: 10

```

The application's constructor creates a `Vector` (line 13) of type `String` with an initial capacity of 10 elements and capacity increment of zero (the defaults for a `Vector`). Note that `Vector` is a generic class, which takes one argument that specifies the type of the elements stored in the `Vector`. A capacity increment of zero indicates that this `Vector` will double in size each time it needs to grow to accommodate more elements. Class `Vector` provides three other constructors. The constructor that takes one integer argument creates an

empty `Vector` with the `initialCapacity` specified by that argument. The constructor that takes two arguments creates a `Vector` with the initial capacity specified by the first argument and the `capacityIncrement` specified by the second argument. Each time the `Vector` needs to grow, it will add space for the specified number of elements in the capacity increment. The constructor that takes a `Collection` creates a copy of a collection's elements and stores them in the `Vector`.

---

[Page 921]

Line 18 calls `Vector` method `add` to add objects (`Strings` in this program) to the end of the `Vector`. If necessary, the `Vector` increases its capacity to accommodate the new element. Class `Vector` also provides a method `add` that takes two arguments. This method takes an object and an integer and inserts the object at the specified index in the `Vector`. Method `set` will replace the element at a specified position in the `Vector` with a specified element. Method `insertElementAt` provides the same functionality as the method `add` that takes two arguments, except that the order of the parameters is reversed.

Line 25 calls `Vector` method `firstElement` to return a reference to the first element in the `Vector`. Line 26 calls `Vector` method `lastElement` to return a reference to the last element in the `Vector`. Each of these methods throws a `NoSuchElementException` if there are no elements in the `Vector` when the method is called.

Line 35 calls `Vector` method `contains` to determine whether the `Vector` contains `"red"`. The method returns `true` if its argument is in the `Vector`; otherwise, the method returns `false`. Method `contains` uses `Object` method `equals` to determine whether the search key is equal to one of the `Vector`'s elements. Many classes override method `equals` to perform the comparisons in a manner specific to those classes. For example, class `String` declares `equals` to compare the individual characters in the two `Strings` being compared. If method `equals` is not overridden, the original version of method `equals` inherited from class `Object` is used.

---

[Page 922]

## Common Programming Error 19.4

*Without overriding method `equals`, the program performs comparisons using operator `==` to determine whether two references refer to the same object in memory.*

Line 37 calls `Vector` method `indexOf` to determine the index of the first location in the `Vector` that contains the argument. The method returns `-1` if the argument is not found in the `Vector`. An overloaded version of this method takes a second argument specifying the index in the `Vector` at which the search should begin.

## Performance Tip 19.6

*`Vector` methods `contains` and `indexOf` perform linear searches of a `Vector`'s contents. These searches are inefficient for large `Vectors`. If a program frequently searches for elements in a collection, consider using one of the Java Collection API's `Map` implementations ([Section 19.10](#)), which provide high-speed searching capabilities.*

Line 41 calls `Vector` method `remove` to remove the first occurrence of its argument from the `Vector`. The

method returns `true` if it finds the element in the `Vector`; otherwise, the method returns `false`. If the element is removed, all elements after that element in the `Vector` shift one position toward the beginning of the `Vector` to fill in the position of the removed element. Class `Vector` also provides method `removeAllElements` to remove every element from a `Vector` and method `removeElementAt` to remove the element at a specified index.

Lines 5354 use `Vector` methods `size` and `capacity` to determine the number of elements currently in the `Vector` and the number of elements that can be stored in the `Vector` without allocating more memory, respectively.

Line 59 calls `Vector` method `isEmpty` to determine whether the `Vector` is empty. The method returns `True` if there are no elements in the `Vector`; otherwise, the method returns `false`. Lines 6667 use the enhanced `for` statement to print out all elements in the vector.

Among the methods introduced in [Fig. 19.6](#), `firstElement`, `lastElement` and `capacity` can be used only with `Vector`. Other methods (e.g., `add`, `contains`, `indexOf`, `remove`, `size` and `isEmpty`) are declared by `List`, which means that they can be used by any class that implements `List`, such as `Vector`.

## 19.6. Collections Algorithms

The collections framework provides several high-performance algorithms for manipulating collection elements. These algorithms are implemented as `static` methods of class `Collections` (Fig. 19.7). Algorithms `sort`, `binarySearch`, `reverse`, `shuffle`, `fill` and `copy` operate on `Lists`. Algorithms `min`, `max`, `addAll`, `frequency` and `disjoint` operate on `Collections`.

Figure 19.7. Collections algorithms.

| Algorithm                 | Description                                                                        |
|---------------------------|------------------------------------------------------------------------------------|
| <code>sort</code>         | Sorts the elements of a <code>List</code> .                                        |
| <code>binarySearch</code> | Locates an object in a <code>List</code> .                                         |
| <code>reverse</code>      | Reverses the elements of a <code>List</code> .                                     |
| <code>shuffle</code>      | Randomly orders a <code>List</code> 's elements.                                   |
| <code>fill</code>         | Sets every <code>List</code> element to refer to a specified object.               |
| <code>copy</code>         | Copies references from one <code>List</code> into another.                         |
| <code>min</code>          | Returns the smallest element in a <code>Collection</code> .                        |
| <code>max</code>          | Returns the largest element in a <code>Collection</code> .                         |
| <code>addAll</code>       | Appends all elements in an array to a collection.                                  |
| <code>frequency</code>    | Calculates how many elements in the collection are equal to the specified element. |
| <code>disjoint</code>     | Determines whether two collections have no elements in common.                     |

### Software Engineering Observation 19.4

*The collections framework algorithms are polymorphic. That is, each algorithm can operate on objects that implement specific interfaces, regardless of the underlying implementations.*

#### 19.6.1. Algorithm `sort`

Algorithm `sort` sorts the elements of a `List`, which must implement the `Comparable` interface. The order is

determined by the natural order of the elements' type as implemented by its class's `compareTo` method. Method `compareTo` is declared in interface `Comparable` and is sometimes called the **natural comparison method**. The `sort` call may specify as a second argument a `Comparator` object that determines an alternative ordering of the elements.

## Sorting in Ascending Order

[Figure 19.8](#) uses algorithm `sort` to order the elements of a `List` in ascending order (line 20). Recall that `List` is a generic type and accepts one type argument that specifies the list element type. Line 15 declares `list` as a `List` of `String`. Note that lines 18 and 23 each use an implicit call to the `list`'s `toString` method to output the list contents in the format shown on the second and fourth lines of the output.

Figure 19.8. `Collections` method `sort`.

(This item is displayed on page 924 in the print version)

```
1 // Fig. 19.8: Sort1.java
2 // Using algorithm sort.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.Collections;
6
7 public class Sort1
8 {
9 private static final String suits[] =
10 { "Hearts", "Diamonds", "Clubs", "Spades" };
11
12 // display array elements
13 public void printElements()
14 {
15 List< String > list = Arrays.asList(suits); // create List
16
17 // output list
18 System.out.printf("Unsorted array elements:\n%s\n", list);
19
20 Collections.sort(list); // sort ArrayList
21
22 // output list
23 System.out.printf("Sorted array elements:\n%s\n", list);
24 } // end method printElements
25
26 public static void main(String args[])
27 {
28 Sort1 sort1 = new Sort1();
29 sort1.printElements();
30 } // end main
31 } // end class Sort1
```

```
Unsorted array elements:
[Hearts, Diamonds, Clubs, Spades]
Sorted array elements:
[Clubs, Diamonds, Hearts, Spades]
```

## Sorting in Descending Order

[Figure 19.9](#) sorts the same list of strings used in [Fig. 19.8](#) in descending order. The example introduces the `Comparator` interface, which is used for sorting a `Collection`'s elements in a different order. Line 21 calls `Collections`'s method `sort` to order the `List` in descending order. The static `Collections` method `reverseOrder` returns a `Comparator` object that orders the collection's elements in reverse order.

Figure 19.9. `Collections` method `sort` with a `Comparator` object.

(This item is displayed on pages 924 - 925 in the print version)

```
1 // Fig. 19.9: Sort2.java
2 // Using a Comparator object with algorithm sort.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.Collections;
6
7 public class Sort2
8 {
9 private static final String suits[] =
10 { "Hearts", "Diamonds", "Clubs", "Spades" };
11
12 // output List elements
13 public void printElements()
14 {
15 List list = Arrays.asList(suits); // create List
16
17 // output List elements
18 System.out.printf("Unsorted array elements:\n%s\n", list);
19
20 // sort in descending order using a comparator
21 Collections.sort(list, Collections.reverseOrder());
22
23 // output List elements
24 System.out.printf("Sorted list elements:\n%s\n", list);
25 } // end method printElements
26
27 public static void main(String args[])
28 {
29 Sort2 sort2 = new Sort2();
30 sort2.printElements();
31 } // end main
32 } // end class Sort2
```

```
Unsorted array elements:
[Hearts, Diamonds, Clubs, Spades]
Sorted list elements:
[Spades, Hearts, Diamonds, Clubs]
```

[Page 925]

## Sorting with a **Comparator**

[Figure 19.10](#) creates a custom **Comparator** class, named **TimeComparator**, that implements interface **Comparator** to compare two **Time2** objects. Class **Time2**, declared in [Fig. 8.5](#), represents times with hours, minutes and seconds.

Figure 19.10. Custom **Comparator** class that compares two **Time2** objects.

(This item is displayed on page 926 in the print version)

```
1 // Fig. 19.10: TimeComparator.java
2 // Custom Comparator class that compares two Time2 objects.
3 import java.util.Comparator;
4
5 public class TimeComparator implements Comparator< Time2 >
6 {
7 public int compare(Time2 tim1, Time2 time2)
8 {
9 int hourCompare = tim1.getHour() - time2.getHour(); // compare hour
10
11 // test the hour first
12 if (hourCompare != 0)
13 return hourCompare;
14
15 int minuteCompare =
16 tim1.getMinute() - time2.getMinute(); // compare minute
17
18 // then test the minute
19 if (minuteCompare != 0)
20 return minuteCompare;
21
22 int secondCompare =
23 tim1.getSecond() - time2.getSecond(); // compare second
24
25 return secondCompare; // return result of comparing seconds
26 } // end method compare
27 } // end class TimeComparator
```

Class **TimeComparator** implements interface **Comparator**, a generic type that takes one argument (in this case **Time2**). Method **compare** (lines 726) performs comparisons between **Time2** objects. Line 9 compares the two hours of the **Time2** objects. If the hours are different (line 12), then we return this value. If this value is

positive, then the first hour is greater than the second and the first time is greater than the second. If this value is negative, then the first hour is less than the second and the first time is less than the second. If this value is zero, the hours are the same and we must test the minutes (and maybe the seconds) to determine which time is greater.

[Figure 19.11](#) sorts a list using the custom `Comparator` class `TimeComparator`. Line 11 creates an `ArrayList` of `Time2` objects. Recall that both `ArrayList` and `List` are generic types and accept a type argument that specifies the element type of the collection. Lines 13-17 create five `Time2` objects and add them to this list. Line 23 calls method `sort`, passing it an object of our `TimeComparator` class ([Fig. 19.10](#)).

Figure 19.11. `Collections` method `sort` with a custom `Comparator` object.

(This item is displayed on pages 926 - 927 in the print version)

Sorted list elements:
[6:05:34 AM, 6:24:22 AM, 6:24:34 AM, 12:14:58 PM, 6:14:58 PM]
```

[Page 927]

## 19.6.2. Algorithm `shuffle`

Algorithm `shuffle` randomly orders a `List`'s elements. In [Chapter 7](#), we presented a card shuffling and dealing simulation that used a loop to shuffle a deck of cards. In [Fig. 19.12](#), we use algorithm `shuffle` to shuffle a deck of `Card` objects that might be used in a card game simulator.

Figure 19.12. Card shuffling and dealing with `Collections` method `shuffle`.

(This item is displayed on pages 927 - 929 in the print version)

```

| Nine of Spades    | Nine of Clubs     |
| King of Spades    | Ace of Diamonds   |
| Ten of Hearts     | Ace of Hearts     |
| Queen of Clubs    | Deuce of Spades   |
| Three of Diamonds | King of Clubs     |
| Four of Clubs     | Jack of Diamonds  |
| Eight of Spades   | Five of Spades    |
| Jack of Hearts    | Deuce of Diamonds |

Class `Card` (lines 841) represents a card in a deck of cards. Each `Card` has a face and a suit. Lines 1012 declare two `enum` types `Face` and `Suit` which represent the face and the suit of the card, respectively. Method `toString` (lines 3740) returns a `String` containing the face and suit of the `Card` separated by the string " of ". When an `enum` constant is converted to a string, the constant's identifier is used as the string representation. Normally we would use all uppercase letters for `enum` constants. In this example, we chose to use capital letters for only the first letter of each `enum` constant because we want the card to be displayed with initial capital letters for the face and the suit (e.g., "Ace of Spades").

---

[Page 929]

Lines 5562 populate the `deck` array with cards that have unique face and suit combinations. Both `Face` and `Suit` are `public static enum` types of class `Card`. To use these `enum` types outside of class `Card`, you must qualify each `enum`'s type name with the name of the class in which it resides (i.e., `Card`) and a dot (.) separator. Hence, lines 55 and 57 use `Card.Suit` and `Card.Face` to declare the control variables of the `for` statements. Recall that method `values` of an `enum` type returns an array that contains all the constants of the `enum` type. Lines 5562 use enhanced `for` statements to construct 52 new `Cards`.

---

[Page 930]

The shuffling occurs in line 65, which calls `static` method `shuffle` of class `Collections` to shuffle the elements of the array. Method `shuffle` requires a `List` argument, so we must obtain a `List` view of the array before we can shuffle it. Line 64 invokes `static` method `asList` of class `Arrays` to get a `List` view of the `deck` array.

Method `printCards` (lines 6975) displays the deck of cards in two columns. In each iteration of the loop,

lines 7374 output a card left justified in a 20-character field followed by either a newline or an empty string based on the number of cards output so far. If the number of cards is even, a newline is output; otherwise, a tab is output.

### 19.6.3. Algorithms **reverse**, **fill**, **copy**, **max** and **min**

Class **Collections** provides algorithms for reversing, filling and copying **Lists**. Algorithm **reverse** reverses the order of the elements in a **List**, and algorithm **fill** overwrites elements in a **List** with a specified value. The **fill** operation is useful for reinitializing a **List**. Algorithm **copy** takes two arguments a destination **List** and a source **List**. Each source **List** element is copied to the destination **List**. The destination **List** must be at least as long as the source **List**; otherwise, an **IndexOutOfBoundsException** occurs. If the destination **List** is longer, the elements not overwritten are unchanged.

Each of the algorithms we have seen so far operates on **Lists**. Algorithms **min** and **max** each operate on any **Collection**. Algorithm **min** returns the smallest element in a **Collection**, and algorithm **max** returns the largest element in a **Collection**. Both of these algorithms can be called with a **Comparator** object as a second argument to perform custom comparisons of objects, such as the **TimeComparator** in [Fig. 19.11](#). [Figure 19.13](#) demonstrates the use of algorithms **reverse**, **fill**, **copy**, **min** and **max**. Note that the generic type **List** is declared to store **CharacterS**.

Figure 19.13. **Collections** methods **reverse**, **fill**, **copy**, **max** and **min**.

(This item is displayed on pages 930 - 931 in the print version)

```
1 // Fig. 19.13: Algorithms1.java
2 // Using algorithms reverse, fill, copy, min and max.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.Collections;
6
7 public class Algorithms1
8 {
9 private Character[] letters = { 'P', 'C', 'M' };
10 private Character[] lettersCopy;
11 private List< Character > list;
12 private List< Character > copyList;
13
14 // create a List and manipulate it with methods from Collections
15 public Algorithms1()
16 {
17 list = Arrays.asList(letters); // get List
18 lettersCopy = new Character[3];
19 copyList = Arrays.asList(lettersCopy); // list view of lettersCopy
20
21 System.out.println("Initial list: ");
22 output(list);
23
24 Collections.reverse(list); // reverse order
25 System.out.println("\nAfter calling reverse: ");
26 output(list);
27
28 Collections.copy(copyList, list); // copy List
29 System.out.println("\nAfter copying: ");
30 output(copyList);
31
32 Collections.fill(list, 'R'); // fill list with Rs
33 System.out.println("\nAfter calling fill: ");
```

```

34 output(list);
35 } // end Algorithms1 constructor
36
37 // output List information
38 private void output(List< Character > listRef)
39 {
40 System.out.print("The list is: ");
41
42 for (Character element : listRef)
43 System.out.printf("%s ", element);
44
45 System.out.printf("\nMax: %s", Collections.max(listRef));
46 System.out.printf(" Min: %s\n", Collections.min(listRef));
47 } // end method output
48
49 public static void main(String args[])
50 {
51 new Algorithms1();
52 } // end main
53 } // end class Algorithms1

```

```

Initial list:
The list is: P C M
Max: P Min: C

After calling reverse:
The list is: M C P
Max: P Min: C

After copying:
The list is: M C P
Max: P Min: C

After calling fill:
The list is: R R R
Max: R Min: R

```

Line 24 calls `Collections` method `reverse` to reverse the order of `list`. Method `reverse` takes one `List` argument. In this case, `list` is a `List` view of array `letters`. Array `letters` now has its elements in reverse order. Line 28 copies the elements of `list` into `copyList`, using `Collections` method `copy`. Changes to `copyList` do not change `letters`, because `copyList` is a separate `List` that is not a `List` view for `letters`. Method `copy` requires two `List` arguments. Line 32 calls `Collections` method `fill` to place the string "R" in each element of `list`. Because `list` is a `List` view of `letters`, this operation changes each element in `letters` to "R". Method `fill` requires a `List` for the first argument and an `Object` for the second argument. Lines 45-46 call `Collections` methods `max` and `min` to find the largest and the smallest element of the collection, respectively. Recall that a `List` is a `Collection`, so lines 45-46 can pass a `List` to methods `max` and `min`.

## 19.6.4. Algorithm `binarySearch`

In [Section 16.2.2](#), we studied the high-speed binary-search algorithm. This algorithm is built into the Java collections framework as a `static` method of class `Collections`. The `binarySearch` algorithm locates an object in a `List` (i.e., a `LinkedList`, a `Vector` or an `ArrayList`). If the object is found, its index is returned. If the object is not found, `binarySearch` returns a negative value. Algorithm `binarySearch` determines this negative value by first calculating the insertion point and making its sign negative. Then, `binarySearch` subtracts 1 from the insertion point to obtain the return value, which guarantees that method `binarySearch` returns positive numbers ( $\geq 0$ ) if and only if the object is found. If multiple elements in the list match the search key, there is no guarantee which one will be located first. [Figure 19.14](#) uses the `binarySearch` algorithm to search for a series of strings in an `ArrayList`.

Figure 19.14. `Collections` method `binarySearch`.

(This item is displayed on pages 932 - 933 in the print version)

```
1 // Fig. 19.14: BinarySearchTest.java
2 // Using algorithm binarySearch.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.Collections;
6 import java.util.ArrayList;
7
8 public class BinarySearchTest
9 {
10 private static final String colors[] = { "red", "white",
11 "blue", "black", "yellow", "purple", "tan", "pink" };
12 private List< String > list; // ArrayList reference
13
14 // create, sort and output list
15 public BinarySearchTest()
16 {
17 list = new ArrayList< String >(Arrays.asList(colors));
18 Collections.sort(list); // sort the ArrayList
19 System.out.printf("Sorted ArrayList: %s\n", list);
20 } // end BinarySearchTest constructor
21
22 // search list for various values
23 private void search()
24 {
25 printSearchResults(colors[3]); // first item
26 printSearchResults(colors[0]); // middle item
27 printSearchResults(colors[7]); // last item
28 printSearchResults("aqua"); // below lowest
29 printSearchResults("gray"); // does not exist
30 printSearchResults("teal"); // does not exist
31 } // end method search
32
33 // perform searches and display search result
34 private void printSearchResults(String key)
35 {
36 int result = 0;
37
38 System.out.printf("\nSearching for: %s\n", key);
39 result = Collections.binarySearch(list, key);
40
41 if (result >= 0)
```

```

42 System.out.printf("Found at index %d\n", result);
43 else
44 System.out.printf("Not Found (%d)\n",result);
45 } // end method printSearchResults
46
47 public static void main(String args[])
48 {
49 BinarySearchTest binarySearchTest = new BinarySearchTest();
50 binarySearchTest.search();
51 } // end main
52 } // end class BinarySearchTest

```

```

Sorted ArrayList: [black, blue, pink, purple, red, tan, white, yellow]

Searching for: black
Found at index 0

Searching for: red
Found at index 4

Searching for: pink
Found at index 2

Searching for: aqua
Not Found (-1)

Searching for: gray
Not Found (-3)

Searching for: teal
Not Found (-7)

```

Recall that both `List` and `ArrayList` are generic types (lines 12 and 17). `Collections` method `binarySearch` expects the list's elements to be sorted in ascending order, so line 18 in the constructor sorts the list with `Collections` method `sort`. If the list's elements are not sorted, the result is undefined. Line 19 outputs the sorted list. Method `search` (lines 2331) is called from `main` to perform the searches. Each search calls method `printSearchResults` (lines 3445) to perform the search and output the results. Line 39 calls `Collections` method `binarySearch` to search `list` for the specified `key`. Method `binarySearch` takes a `List` as the first argument and an `Object` as the second argument. Lines 4144 output the results of the search. An overloaded version of `binarySearch` takes a `Comparator` object as its third argument, which specifies how `binarySearch` should compare elements.

### 19.6.5. Algorithms `addAll`, `frequency` and `disjoint`

Among others, J2SE 5.0 includes three new algorithms in class `Collections`, namely `addAll`, `frequency` and `disjoint`. Algorithm `addAll` takes two arguments a `Collection` into which to insert the new element(s) and an array that provides elements to be inserted. Algorithm `frequency` takes two arguments a `Collection` to be searched and an `Object` to be searched for in the collection. Method `frequency` returns the number of

times that the second argument appears in the collection. Algorithm `disjoint` takes two `Collections` and returns `true` if they have no elements in common. [Figure 19.15](#) demonstrates the use of algorithms `addAll`, `frequency` and `disjoint`.

Figure 19.15. `Collections` method `addAll`, `frequency` and `disjoint`.

(This item is displayed on pages 934 - 935 in the print version)

```
1 // Fig. 19.15: Algorithms2.java
2 // Using algorithms addAll, frequency and disjoint.
3 import java.util.List;
4 import java.util.Vector;
5 import java.util.Arrays;
6 import java.util.Collections;
7
8 public class Algorithms2
9 {
10 private String[] colors = { "red", "white", "yellow", "blue" };
11 private List< String > list;
12 private Vector< String > vector = new Vector< String >();
13
14 // create List and Vector
15 // and manipulate them with methods from Collections
16 public Algorithms2()
17 {
18 // initialize list and vector
19 list = Arrays.asList(colors);
20 vector.add("black");
21 vector.add("red");
22 vector.add("green");
23
24 System.out.println("Before addAll, vector contains: ");
25
26 // display elements in vector
27 for (String s : vector)
28 System.out.printf("%s ", s);
29
30 // add elements in colors to list
31 Collections.addAll(vector, colors);
32
33 System.out.println("\n\nAfter addAll, vector contains: ");
34
35 // display elements in vector
36 for (String s : vector)
37 System.out.printf("%s ", s);
38
39 // get frequency of "red"
40 int frequency = Collections.frequency(vector, "red");
41 System.out.printf(
42 "\n\nFrequency of red in vector: %d\n", frequency);
43
44 // check whether list and vector have elements in common
45 boolean disjoint = Collections.disjoint(list, vector);
46
47 System.out.printf("\nlist and vector %s elements in common\n",
48 (disjoint ? "do not have" : "have"));
49 } // end Algorithms2 constructor
50 }
```

```
51 public static void main(String args[])
52 {
53 new Algorithms2();
54 } // end main
55 } // end class Algorithms2
```

Before addAll, vector contains:  
black red green

After addAll, vector contains:  
black red green red white yellow blue

Frequency of red in vector: 2

list and vector have elements in common

[Page 935]

Line 19 initializes `list` with elements in array `colors`, and lines 20-22 add `Strings` "black", "red" and "green" to `vector`. Line 31 invokes method `addAll` to add elements in array `colors` to `vector`. Line 40 gets the frequency of `String` "red" in `Collection` `vector` using method `frequency`. Note that lines 41-42 use the new `printf` method to print the frequency. Line 45 invokes method `disjoint` to test whether `Collections` `list` and `vector` have elements in common.

## 19.7. **Stack** Class of Package **java.util**

In [Chapter 17](#), Data Structures, we learned how to build fundamental data structures, including linked lists, stacks, queues and trees. In a world of software reuse, rather than building data structures as we need them, we can often take advantage of existing data structures. In this section, we investigate class **Stack** in the Java utilities package (**java.util**).

[Section 19.5.3](#) discussed class **Vector**, which implements a dynamically resizable array. Class **Stack** extends class **Vector** to implement a stack data structure. Autoboxing occurs when you add a primitive type to a **Stack**, because class **Stack** stores only references to objects. [Figure 19.16](#) demonstrates several **Stack** methods. For the details of class **Stack**, visit [java.sun.com/j2se/5.0/docs/api/java/util/Stack.html](http://java.sun.com/j2se/5.0/docs/api/java/util/Stack.html).

Figure 19.16. **Stack** class of package **java.util**.

(This item is displayed on pages 936 - 937 in the print version)

[Page 937]

Line 10 of the constructor creates an empty `Stack` of type `Number`. Class `Number` (in package `java.lang`) is the superclass of most wrapper classes (e.g., `Integer`, `Double`) for the primitive types. By creating a `Stack` of `Number`, objects of any class that extends the `Number` class can be pushed onto the stack. Lines 19, 21, 23 and 25 each call `Stack` method `push` to add objects to the top of the stack. Note the literals `12L` (line 13) and `1.0F` (line 15). Any integer literal that has the suffix `L` is a `long` value. An integer literal without a suffix is an `int` value. Similarly, any floating-point literal that has the suffix `F` is a `float` value. A floating-point literal without a suffix is a `double` value. You can learn more about numeric literals in the *Java Language Specification* at [java.sun.com/docs/books/jls/second\\_edition/html/expressions.doc.html#224125](http://java.sun.com/docs/books/jls/second_edition/html/expressions.doc.html#224125).

[Page 938]

An infinite loop (lines 3439) calls `Stack` method `pop` to remove the top element of the stack. The method returns a `Number` reference to the removed element. If there are no elements in the `Stack`, method `pop` throws an `EmptyStackException`, which terminates the loop. Class `Stack` also declares method `peek`. This method returns the top element of the stack without popping the element off the stack.

Line 49 calls `Stack` method `isEmpty` (inherited by `Stack` from class `Vector`) to determine whether the stack is empty. If it is empty, the method returns `true`; otherwise, the method returns `false`.

Method `printStack` (lines 4761) uses the enhanced `for` statement to iterate through the elements in the stack. The current top of the stack (the last value pushed onto the stack) is the first value printed. Because class `Stack` extends class `Vector`, the entire `public` interface of class `Vector` is available to clients of class `Stack`.

## Error-Prevention Tip 19.1

*Because `Stack` extends `Vector`, all public `Vector` methods can be called on `Stack` objects, even if the methods do not represent conventional stack operations. For example, `Vector` method `add` can be used to insert an element anywhere in a stackan operation that could "corrupt" the stack. When manipulating a `Stack`, only methods `push` and `pop` should be used to add elements to and remove elements from the `Stack`, respectively.*

## 19.8. Class `PriorityQueue` and Interface `Queue`

In [Section 17.8](#), we introduced the queue data structure and created our own implementation of it. In this section we investigate interface `Queue` and class `PriorityQueue` in the Java utilities package (`java.util`). `Queue`, a new collection interface introduced in J2SE 5.0, extends interface `Collection` and provides additional operations for inserting, removing and inspecting elements in a queue. `PriorityQueue`, one of the classes that implements the `Queue` interface, orders elements by their natural ordering as specified by `Comparable` elements' `compareTo` method or by a `Comparator` object that is supplied through the constructor.

Class `PriorityQueue` provides functionality that enables insertions in sorted order into the underlying data structure and deletions from the front of the underlying data structure. When adding elements to a `PriorityQueue`, the elements are inserted in priority order such that the highest-priority element (i.e., the largest value) will be the first element removed from the `PriorityQueue`.

The common `PriorityQueue` operations are `offer` to insert an element at the appropriate location based on priority order, `poll` to remove the highest-priority element of the priority queue (i.e., the head of the queue), `peek` to get a reference to the highest-priority element of the priority queue (without removing that element), `clear` to remove all elements in the priority queue and `size` to get the number of elements in the priority queue. [Figure 19.17](#) demonstrates the `PriorityQueue` class.

Figure 19.17. `PriorityQueue` test program.

(This item is displayed on page 939 in the print version)

```
1 // Fig. 19.17: PriorityQueueTest.java
2 // Standard library class PriorityQueue test program.
3 import java.util.PriorityQueue;
4
5 public class PriorityQueueTest
6 {
7 public static void main(String args[])
8 {
9 // queue of capacity 11
10 PriorityQueue< Double > queue = new PriorityQueue< Double >();
11
12 // insert elements to queue
13 queue.offer(3.2);
14 queue.offer(9.8);
15 queue.offer(5.4);
16
17 System.out.print("Polling from queue: ");
18
19 // display elements in queue
20 while (queue.size() > 0)
21 {
22 System.out.printf("%.1f ", queue.peek()); // view top element
23 queue.poll(); // remove top element
24 } // end while
25 } // end main
26 } // end class PriorityQueueTest
```

```
Polling from queue: 3.2 5.4 9.8
```

Line 10 creates a `PriorityQueue` that stores `Doubles` with an initial capacity of `11` elements and orders the elements according to the object's natural ordering (the defaults for a `PriorityQueue`). Note that `PriorityQueue` is a generic class and that line 10 instantiates a `PriorityQueue` with a type argument `Double`. Class `PriorityQueue` provides five additional constructors. One of these takes an `int` and a `Comparator` object to create a `PriorityQueue` with the initial capacity specified by the `int` and the ordering by the `Comparator`. Lines 13-15 use method `offer` to add elements to the priority queue. Method `offer` throws a `NullPointerException` if the program attempts to add a `null` object to the queue. The loop in lines 20-24 use method `size` to determine whether the priority queue is empty (line 20). While there are more elements, line 22 uses `PriorityQueue` method `peek` to retrieve the highest-priority element in the queue for output (without actually removing the element from the queue). Line 23 removes the highest-priority element in the queue with method `poll`.

## 19.9. Sets

A **Set** is a **Collection** that contains unique elements (i.e., no duplicate elements). The collections framework contains several **Set** implementations, including **HashSet** and **TreeSet**. **HashSet** stores its elements in a hash table, and **TreeSet** stores its elements in a tree. The concept of hash tables is presented in [Section 19.10](#). [Figure 19.18](#) uses a **HashSet** to remove duplicate strings from a **List**. Recall that both **List** and **Collection** are generic types, so line 18 creates a **List** that contains **String** objects, and line 24 passes a **Collection** of **Strings** to method `printNonDuplicates`.

Figure 19.18. **HashSet** used to remove duplicate values from array of strings.

(This item is displayed on page 940 in the print version)

```
1 // Fig. 19.18: SetTest.java
2 // Using a HashSet to remove duplicates.
3 import java.util.List;
4 import java.util.Arrays;
5 import java.util.HashSet;
6 import java.util.Set;
7 import java.util.Collection;
8
9 public class SetTest
10 {
11 private static final String colors[] = { "red", "white", "blue",
12 "green", "gray", "orange", "tan", "white", "cyan",
13 "peach", "gray", "orange" };
14
15 // create and output ArrayList
16 public SetTest()
17 {
18 List< String > list = Arrays.asList(colors);
19 System.out.printf("ArrayList: %s\n", list);
20 printNonDuplicates(list);
21 } // end SetTest constructor
22
23 // create set from array to eliminate duplicates
24 private void printNonDuplicates(Collection< String > collection)
25 {
26 // create a HashSet
27 Set< String > set = new HashSet< String >(collection);
28
29 System.out.println("\nNonDuplicates are: ");
30
31 for (String s : set)
32 System.out.printf("%s ", s);
33
34 System.out.println();
35 } // end method printNonDuplicates
36
37 public static void main(String args[])
38 {
39 new SetTest();
```

```

40 } // end main
41 } // end class SetTest

```

ArrayList: [red, white, blue, green, gray, orange, tan, white, cyan, peach, gray, orange]

Nonduplicates are:

red cyan white tan gray green orange blue peach

Method `printNonDuplicates` (lines 2435), which is called from the constructor, takes a `Collection` argument. Line 27 constructs a `HashSet` from the `Collection` argument. Note that both `Set` and `HashSet` are generic types. By definition, `Sets` do not contain any duplicates, so when the `HashSet` is constructed, it removes any duplicates in the `Collection`. Lines 3132 output elements in the `Set`.

[Page 940]

## Sorted Sets

The collections framework also includes interface `SortedSet` (which extends `Set`) for sets that maintain their elements in sorted order either the elements' natural order (e.g., numbers are in ascending order) or an order specified by a `Comparator`. Class `treeSet` implements `SortedSet`. The program in [Fig. 19.19](#) places strings into a `treeSet`. The strings are sorted as they are added to the `treeSet`. This example also demonstrates [range-view methods](#), which enable a program to view a portion of a collection.

[Page 941]

Figure 19.19. Using `SortedSets` and `treeSets`.

(This item is displayed on pages 941 - 942 in the print version)

```

1 // Fig. 19.19: SortedSetTest.java
2 // Using TreeSet and SortedSet.
3 import java.util.Arrays;
4 import java.util.SortedSet;
5 import java.util.TreeSet;
6
7 public class SortedSetTest
8 {
9 private static final String names[] = { "yellow", "green",
10 "black", "tan", "grey", "white", "orange", "red", "green" };
11
12 // create a sorted set with TreeSet, then manipulate it
13 public SortedSetTest()
14 {
15 // create TreeSet
16 SortedSet< String > tree =
17 new TreeSet< String >(Arrays.asList(names));
18

```

```

19 System.out.println("sorted set: ");
20 printSet(tree); // output contents of tree
21
22 // get headSet based on "orange"
23 System.out.print("\nheadSet (\"orange\"): ");
24 printSet(tree.headSet("orange"));
25
26 // get tailSet based upon "orange"
27 System.out.print("tailSet (\"orange\"): ");
28 printSet(tree.tailSet("orange"));
29
30 // get first and last elements
31 System.out.printf("first: %s\n", tree.first());
32 System.out.printf("last : %s\n", tree.last());
33 } // end SortedSetTest constructor
34
35 // output set
36 private void printSet(SortedSet< String > set)
37 {
38 for (String s : set)
39 System.out.printf("%s ", s);
40
41 System.out.println();
42 } // end method printSet
43
44 public static void main(String args[])
45 {
46 new SortedSetTest();
47 } // end main
48 } // end class SortedSetTest

```

```

sorted set:
black green grey orange red tan white yellow

headSet ("orange"): black green grey
tailSet ("orange"): orange red tan white yellow
first: black
last : yellow

```

Lines 1617 of the constructor create a `TReeSet` of `String` that contains the elements of array `names` and assigns the `SortedSet` to the reference `tree`. Both `SortedSet` and `TReeSet` are generic types. Line 20 outputs the initial set of strings using method `printSet` (lines 3642), which we discuss momentarily. Line 24 calls `treeSet` method `headSet` to get a subset of the `TReeSet` in which every element is less than `"orange"`. The view returned from `headSet` is then output with `printSet`. If any changes are made to the subset, they will also be made to the original `treeSet` because the subset returned by `headSet` is a view of the `TReeSet`.

Line 28 calls `treeSet` method `tailSet` to get a subset in which each element is greater than or equal to `"orange"`. The view returned by `tailSet` is then output. Any changes made through the `tailSet` view are made to the original `treeSet`. Lines 3132 call `SortedSet` methods `first` and `last` to get the smallest and largest elements of the set, respectively.

Method `printSet` (lines 3642) accepts a `SortedSet` as an argument and prints it. Lines 3839 print each element of the `SortedSet` using the enhanced `for` statement.

[< PREVIOUS](#)[NEXT >](#)

## 19.10. Maps

`Map`s associate keys to values and cannot contain duplicate keys (i.e., each key can map to only one value; this is called **one-to-one mapping**). `Map`s differ from `Sets` in that `Map`s contain keys and values, whereas `Sets` contain only values. Three of the several classes that implement interface `Map` are `Hashtable`, `HashMap` and `TreeMap`. `Hashtables` and `HashMap`s store elements in hash tables, and `TreeMaps` store elements in trees. This section discusses hash tables and provides an example that uses a `HashMap` to store key/value pairs. Interface `SortedMap` extends `Map` and maintains its keys in sorted order either the elements' natural order or an order specified by a `Comparator`. Class `TreeMap` implements `SortedMap`.

### Map Implementation with Hash Tables

Object-oriented programming languages facilitate creating new types. When a program creates objects of new or existing types, it may need to store and retrieve them efficiently. Storing and retrieving information with arrays is efficient if some aspect of your data directly matches a numerical key value and if the keys are unique and tightly packed. If you have 100 employees with nine-digit Social Security numbers and you want to store and retrieve employee data by using the Social Security number as a key, the task would require an array with one billion elements, because there are one billion unique nine-digit numbers (000,000,000999,999,999). This is impractical for virtually all applications that use Social Security numbers as keys. A program that had an array that large could achieve high performance for both storing and retrieving employee records by simply using the Social Security number as the array index.

---

[Page 943]

There are numerous applications that have this problem, namely, that either the keys are of the wrong type (e.g., not positive integers that correspond to array subscripts) or they are of the right type, but sparsely spread over a huge range. What is needed is a high-speed scheme for converting keys such as Social Security numbers, inventory part numbers and the like into unique array indices. Then, when an application needs to store something, the scheme could convert the application's key rapidly into an index, and the record of information could be stored at that slot in the array. Retrieval is accomplished the same way: Once the application has a key for which it wants to retrieve a data record, the application simply applies the conversion to the key; this produces the array index where the data is stored and retrieved.

The scheme we describe here is the basis of a technique called **hashing**. Why the name? When we convert a key into an array index, we literally scramble the bits, forming a kind of "mishmashed," or hashed, number. The number actually has no real significance beyond its usefulness in storing and retrieving a particular data record.

A glitch in the scheme is called a **collision**; this occurs when two different keys "hash into" the same cell (or element) in the array. We cannot store two values in the same space, so we need to find an alternative home for all values beyond the first that hash to a particular array index. There are many schemes for doing this. One is to "hash again" (i.e., to apply another hashing transformation to the key to provide a next candidate cell in the array). The hashing process is designed to distribute the values throughout the table, so the assumption is that an available cell will be found with just a few hashes.

Another scheme uses one hash to locate the first candidate cell. If that cell is occupied, successive cells are searched in order until an available cell is found. Retrieval works the same way: The key is hashed once to determine the initial location and check whether it contains the desired data. If it does, the search is finished. If it does not, successive cells are searched linearly until the desired data is found.

The most popular solution to hash-table collisions is to have each cell of the table be a hash "bucket," typically a linked list of all the key-value pairs that hash to that cell. This is the solution that Java's

`Hashtable` and `HashMap` classes (from package `java.util`) implement. Both `Hashtable` and `HashMap` implement the `Map` interface. The primary differences between them are that `HashMap` is unsynchronized (multiple threads can modify a `HashMap` concurrently), and allows `null` keys and `null` values.

A hash table's **load factor** affects the performance of hashing schemes. The load factor is the ratio of the number of occupied cells in the hash table to the total number of cells in the hash table. The closer this ratio gets to 1.0, the greater the chance of collisions.

## Performance Tip 19.7

*The load factor in a hash table is a classic example of a memory-space/execution-time trade-off: By increasing the load factor, we get better memory utilization, but the program runs slower, due to increased hashing collisions. By decreasing the load factor, we get better program speed, because of reduced hashing collisions, but we get poorer memory utilization, because a larger portion of the hash table remains empty.*

Hash tables are complex to program. Computer science students study hashing schemes in courses called "Data Structures" and "Algorithms." Java provides classes `Hashtable` and `HashMap` to enable programmers to use hashing without having to implement hash table mechanisms. This concept is profoundly important in our study of object-oriented programming. As discussed in earlier chapters, classes encapsulate and hide complexity (i.e., implementation details) and offer user-friendly interfaces. Properly crafting classes to exhibit such behavior is one of the most valued skills in the field of object-oriented programming. [Figure 19.20](#) uses a `HashMap` to count the number of occurrences of each word in a string.

---

[Page 944]

Figure 19.20. `HashMaps` and `Maps`.

(This item is displayed on pages 944 - 945 in the print version)

```
1 // Fig. 19.20: WordTypeCount.java
2 // Program counts the number of occurrences of each word in a string
3 import java.util.StringTokenizer;
4 import java.util.Map;
5 import java.util.HashMap;
6 import java.util.Set;
7 import java.util.TreeSet;
8 import java.util.Scanner;
9
10 public class WordTypeCount
11 {
12 private Map< String, Integer > map;
13 private Scanner scanner;
14
15 public WordTypeCount()
16 {
17 map = new HashMap< String, Integer >(); // create HashMap
18 scanner = new Scanner(System.in); // create scanner
19 createMap(); // create map based on user input
20 displayMap(); // display map content
21 } // end WordTypeCount constructor
```

```

22
23 // create map from user input
24 private void createMap()
25 {
26 System.out.println("Enter a string:"); // prompt for user input
27 String input = scanner.nextLine();
28
29 // create StringTokenizer for input
30 StringTokenizer tokenizer = new StringTokenizer(input);
31
32 // processing input text
33 while (tokenizer.hasMoreTokens()) // while more input
34 {
35 String word = tokenizer.nextToken().toLowerCase(); // get word
36
37 // if the map contains the word
38 if (map.containsKey(word)) // is word in map
39 {
40 int count = map.get(word); // get current count
41 map.put(word, count + 1); // increment count
42 } // end if
43 else
44 map.put(word, 1); // add new word with a count of 1 to map
45 } // end while
46 } // end method createMap
47
48 // display map content
49 private void displayMap()
50 {
51 Set< String > keys = map.keySet(); // get keys
52
53 // sort keys
54 TreeSet< String > sortedKeys = new TreeSet< String >(keys);
55
56 System.out.println("Map contains:\nKey\t\tValue");
57
58 // generate output for each key in map
59 for (String key : sortedKeys)
60 System.out.printf("%-10s%10s\n", key, map.get(key));
61
62 System.out.printf(
63 "\nsize:%d\nisEmpty:%b\n", map.size(), map.isEmpty());
64 } // end method displayMap
65
66 public static void main(String args[])
67 {
68 new WordTypeCount();
69 } // end main
70 } // end class WordTypeCount

```

```
Enter a string:
To be or not to be: that is the question Whether 'tis nobler to suffer
Map contains:
Key Value
'tis 1
be 1
be: 1
is 1

not 1
or 1
question 1
suffer 1
that 1
the 1
to 3
whether 1

size:13
isEmpty:false
```

---

[Page 945]

Line 17 creates an empty `HashMap` with a default initial capacity (16 elements) and a default load factor (0.75) these defaults are built into the implementation of `HashMap`. When the number of occupied slots in the `HashMap` becomes greater than the capacity times the load factor, the capacity is doubled automatically. Note that `HashMap` is a generic class that takes two type arguments. The first type argument specifies the type of key (i.e., `String`), and the second type argument specifies the type of value (i.e., `Integer`). Recall that the type arguments passed to a generic class must be reference types, hence the second type argument is `Integer`, not `int`. Line 18 creates a `Scanner` that reads user input from the standard input stream. Line 19 calls method `createMap` (lines 2446), which uses a `map` to store the number of occurrences of each word in the sentence. Line 27 invokes method `nextLine` of `scanner` to obtain the user input, and line 30 creates a `StringTokenizer` to break the input string into its component individual words. This `StringTokenizer` constructor takes a string argument and creates a `StringTokenizer` for that string and will use the whitespace to separate the string. The condition in the `while` statement in lines 3345 uses `StringTokenizer` method `hasMoreTokens` to determine whether there are more tokens in the string being tokenized. If so, line 35 converts the next token to lowercase letters. The next token is obtained with a call to `StringTokenizer` method `nextToken` that returns a `String`. [Note: [Section 29.6](#) discusses class `StringTokenizer` in detail.] Then line 38 calls `Map` method `containsKey` to determine whether the word is in the map (and thus has occurred previously in the string). If the `Map` does not contain a mapping for the word, line 44 uses `Map` method `put` to create a new entry in the map, with the word as the key and an `Integer` object containing 1 as the value. Note that autoboxing occurs when the program passes integer 1 to method `put`, because the map stores the number of occurrences of the word as `Integer`. If the word does exist in the map, line 40 uses `Map` method `get` to obtain the key's associated value (the count) in the map. Line 41 increments that value and uses `put` to replace the key's associated value in the map. Method `put` returns the prior value associated with the key, or `null` if the key was not in the map.

---

[Page 946]

Method `displayMap` (lines 4964) displays all the entries in the map. It uses `HashMap` method `keySet` (line 51) to get a set of the keys. The keys have type `String` in the `map`, so method `keySet` returns a generic type `Set` with type parameter specified to be `String`. Line 54 creates a `treeSet` of the keys, in which the keys are sorted. The loop in lines 5960 accesses each key and its value in the map. Line 60 displays each key and its

value using format specifier `%-10s` to left justify each key and format specifier `%10s` to right justify each value. Note that the keys are displayed in ascending order. Line 63 calls `Map` method `size` to get the number of key-value pairs in the `Map`. Line 64 calls `isEmpty`, which returns a `boolean` indicating whether the `Map` is empty.

[< PREV](#)[NEXT >](#)

## 19.11. Properties Class

A **Properties** object is a persistent **Hashtable** that normally stores key-value pairs of strings assuming that you use methods **setProperty** and **getProperty** to manipulate the table rather than inherited **Hashtable** methods **put** and **get**. By "persistent," we mean that the **Properties** object can be written to an output stream (possibly a file) and read back in through an input stream. In fact, most objects in Java can be output and input with Java's object serialization, presented in [Chapter 14](#). A common use of **Properties** objects in prior versions of Java was to maintain application-configuration data or user preferences for applications. [Note: The **Preferences API** (package **java.util.prefs**), introduced in Java 1.4, is meant to replace the use of class **Properties**, but is beyond the scope of this book. To learn more, visit [java.sun.com/j2se/5.0/docs/guide/lang/preferences.html](http://java.sun.com/j2se/5.0/docs/guide/lang/preferences.html).]

Class **Properties** extends class **Hashtable**. [Figure 19.21](#) demonstrates several methods of class **Properties**.

Figure 19.21. **Properties** class of package **java.util**.

[Page 947]

Line 16 uses the no-argument constructor to create an empty `Properties` table with no default properties. Class `Properties` also provides an overloaded constructor that receives a reference to a `Properties` object containing default property values. Lines 19 and 20 each call `Properties` method `setProperty` to store a value for the specified key. If the key does not exist in the table, `setProperty` returns `null`; otherwise, it returns the previous value for that key.

Line 41 calls `Properties` method `getProperty` to locate the value associated with the specified key. If the key is not found in this `Properties` object, `getProperty` returns `null`. An overloaded version of this method receives a second argument that specifies the default value to return if `getProperty` cannot locate the key.

Line 57 calls `Properties` method `store` to save the contents of the `Properties` object to the `OutputStream` object specified as the first argument (in this case, `FileOutputStream output`). The second argument, a `String`, is a description of the `Properties` object. Class `Properties` also provides method `list`, which takes a `PrintStream` argument. This method is useful for displaying the list of properties.

---

[Page 949]

Line 75 calls `Properties` method `load` to restore the contents of the `Properties` object from the `InputStream`

specified as the first argument (in this case, a `FileInputStream`). Line 89 calls `Properties` method `keySet` to obtain a `Set` of the property names. Line 94 obtains the value of a property by passing a key to method `getProperty`.

[◀ PREV](#)[NEXT ▶](#)

# 19.12. Synchronized Collections

In [Chapter 23](#), we discuss multithreading. The collections in the collections framework are unsynchronized by default, so they can operate efficiently when multithreading is not required. Because they are unsynchronized, however, concurrent access to a `Collection` by multiple threads could cause indeterminate results or fatal errors. To prevent potential threading problems, synchronization wrappers are used for collections that might be accessed by multiple threads. A `wrapper` object receives method calls, adds thread synchronization (to prevent concurrent access to the collection) and delegates the calls to the wrapped collection object. The `Collections` API provides a set of `static` methods for wrapping collections as synchronized versions. Method headers for the synchronization wrappers are listed in [Fig. 19.22](#). Details about these methods are available at [java.sun.com/j2se/5.0/docs/api/java/util/Collections.html](http://java.sun.com/j2se/5.0/docs/api/java/util/Collections.html). All these methods take a generic type and return a synchronized view of the generic type. For example, the following code creates a synchronized `List` (`list2`) that stores `String` objects:

[Page 950]

```
List< String > list1 = new ArrayList< String >();
List< String > list2 = Collections.synchronizedList(list1);
```

Figure 19.22. Synchronization wrapper methods.

| public static method headers                                            |
|-------------------------------------------------------------------------|
| < T > Collection< T > synchronizedCollection( Collection< T > c )       |
| < T > List< T > synchronizedList( List< T > aList )                     |
| < T > Set< T > synchronizedSet( Set< T > s )                            |
| < T > SortedSet< T > synchronizedSortedSet( SortedSet< T > s )          |
| < K, V > Map< K, V > synchronizedMap( Map< K, V > m )                   |
| < K, V > SortedMap< K, V > synchronizedSortedMap( SortedMap< K, V > m ) |

# 19.13. Unmodifiable Collections

The `Collections` API provides a set of `static` methods that create `unmodifiable wrappers` for collections. Unmodifiable wrappers throw `UnsupportedOperationException` if attempts are made to modify the collection. Headers for these methods are listed in [Fig. 19.23](#). Details about these methods are available at [java.sun.com/j2se/5.0/docs/api/java/util/Collections.html](http://java.sun.com/j2se/5.0/docs/api/java/util/Collections.html). All these methods take a generic type and return an unmodifiable view of the generic type. For example, the following code creates an unmodifiable `List` (`list2`) that stores `String` objects:

```
List< String > list1 = new ArrayList< String >();
List< String > list2 = Collections.unmodifiableList(list1);
```

Figure 19.23. Unmodifiable wrapper methods.

(This item is displayed on page 951 in the print version)

| public static method headers                                            |
|-------------------------------------------------------------------------|
| < T > Collection< T > unmodifiableCollection( Collection< T > c )       |
| < T > List< T > unmodifiableList( List< T > aList )                     |
| < T > Set< T > unmodifiableSet( Set< T > s )                            |
| < T > SortedSet< T > unmodifiableSortedSet( SortedSet< T > s )          |

| < K, V > SortedMap< K, V > unmodifiableSortedMap( SortedMap< K, V > m ) |

## Software Engineering Observation 19.5

*You can use an unmodifiable wrapper to create a collection that offers read-only access to others, while allowing readwrite access to yourself. You do this simply by giving others a reference to the unmodifiable wrapper while retaining for yourself a reference to the original collection.*

## 19.14. Abstract Implementations

The collections framework provides various abstract implementations of `Collection` interfaces from which the programmer can quickly "flesh out" complete customized implementations. These abstract implementations include a thin `Collection` implementation called an `AbstractCollection`, a thin `List` implementation that allows random access to its elements called an `AbstractList`, a thin `Map` implementation called an `AbstractMap`, a thin `List` implementation that allows sequential access to its elements called an `AbstractSequentialList`, a thin `Set` implementation called an `AbstractSet` and a thin `Queue` implementation called `AbstractQueue`. You can learn more about these classes at [java.sun.com/j2se/5.0/docs/api/java/util/package-summary.html](http://java.sun.com/j2se/5.0/docs/api/java/util/package-summary.html).

To write a custom implementation, you can extend the abstract implementation class that best meets your needs, and implement each of the class's `abstract` methods. Then, if your collection is to be modifiable, override any concrete methods that prevent modification.

## 19.15. Wrap-Up

This chapter introduced the Java collections framework. You learned how to use class `Arrays` to perform array manipulations. You learned the collection hierarchy and how to use the collections framework interfaces to program with collections polymorphically. You also learned several predefined algorithms for manipulating collections. In the next chapter, we introduce Java applets, which are Java programs that typically execute in a Web browser. We start with sample applets that come with the JDK, then show you how to write and execute your own applets.

## Summary

- The Java collections framework gives the programmer access to prepackaged data structures as well as to algorithms for manipulating them.
  - A collection is an object that can hold references to other objects. The collection interfaces declare the operations that can be performed on each type of collection.
  - The classes and interfaces of the collections framework are in package `java.util`.
  - Class `Arrays` provides `static` methods for manipulating arrays, including `sort` for sorting an array, `binarySearch` for searching a sorted array, `equals` for comparing arrays and `fill` for placing items in an array.
  - `Arrays` method `asList` returns a `List` view of an array, which enables a program to manipulate the array as if it were a `List`. Any modifications made through the `List` view change the array, and any modifications to the array change the `List` view.
- 

[Page 952]

- Method `size` gets the number of items in a `List`, and method `get` returns a `List` element.
- Interface `Collection` is the root interface in the collection hierarchy from which interfaces `Set` and `List` are derived. Interface `Collection` contains bulk operations for adding, clearing, comparing and retaining objects in a collection. Interface `Collection` provides a method `iterator` for getting an `Iterator`.
- Class `Collections` provides `static` methods for manipulating collections. Many of the methods are implementations of polymorphic algorithms for searching, sorting and so on.
- A `List` is an ordered `Collection` that can contain duplicate elements.
- Interface `List` is implemented by classes `ArrayList`, `LinkedList` and `Vector`. Class `ArrayList` is a resizable-array implementation of a `List`. A `LinkedList` is a linked-list implementation of a `List`.
- `Iterator` method `hasNext` determines whether a `Collection` contains another element. Method `next` returns a reference to the next object in the `Collection` and advances the `Iterator`.
- Method `subList` returns a view of a portion of a `List`. Any changes made to this view are also made to the `List`.
- Method `clear` removes elements from a `List`.
- Method `toArray` returns the contents of a collection as an array.
- Class `Vector` manages dynamically resizable arrays. At any time, a `Vector` contains a number of elements that is less than or equal to its capacity. If a `Vector` needs to grow, it grows by its capacity increment. If no capacity increment is specified, Java doubles the size of the `Vector` each time additional capacity is required. The default capacity is 10 elements.
- `Vector` method `add` adds its argument to the end of the `Vector`. Method `insertElementAt` inserts an element at the specified position. Method `set` sets the element at a specific position.
- `Vector` method `remove` removes the first occurrence of its argument from the `Vector`. Method `removeAllElements` removes every element from the `Vector`. Method `removeElementAt` removes the

element at the specified index.

- `Vector` method `firstElement` returns a reference to the first element. Method `lastElement` returns a reference to the last element.
  - `Vector` method `contains` determines whether the `Vector` contains the `searchKey` specified as an argument. `Vector` method `indexOf` gets the index of the first location of its argument. The method returns `-1` if the argument is not found in the `Vector`.
  - `Vector` method `isEmpty` determines whether the `Vector` is empty. Methods `size` and `capacity` determine the number of elements currently in the `Vector` and the number of elements that can be stored in the `Vector` without allocating more memory, respectively.
  - Algorithms `sort`, `binarySearch`, `reverse`, `shuffle`, `fill` and `copy` operate on `Lists`. Algorithms `min` and `max` operate on `Collections`. Algorithm `reverse` reverses the elements of a `List`, `fill` sets every `List` element to a specified `Object`, and `copy` copies elements from one `List` into another `List`. Algorithm `sort` sorts the elements of a `List`.
  - Algorithms `addAll` appends all the elements in an array to a collection, `frequency` calculates how many elements in the collection are equal to the specified element, and `disjoint` determines whether two collections have elements in common.
  - Algorithms `min` and `max` find the smallest and largest items in a collection.
  - The `Comparator` interface provides a means of sorting a `Collection`'s elements in an order other than their natural order.
  - `Collections` method `reverseOrder` returns a `Comparator` object that can be used with `sort` to sort elements of a collection in reverse order.
- 

[Page 953]

- Algorithm `shuffle` randomly orders the elements of a `List`.
- Algorithm `binarySearch` locates an `Object` in a sorted `List`.
- Class `Stack` extends `Vector`. `Stack` method `push` adds its argument to the top of the stack. Method `pop` removes the top element of the stack. Method `peek` returns a reference to the top element without removing it. `Stack` method `empty` determines whether the stack is empty.
- `Queue`, a new collection interface introduced in J2SE 5.0, extends interface `Collection` and provides additional operations for inserting, removing and inspecting elements in a queue.
- `PriorityQueue`, one of the `Queue` implementations, orders elements by their natural ordering (i.e., the implementation of the `compareTo` method) or by a `Comparator` object that is supplied through the constructor.
- The common `PriorityQueue` operations are `offer` to insert an element at the appropriate location based on priority order, `poll` to remove the highest-priority element of the priority queue (i.e., the head of the queue), `peek` to get a reference to the highest-priority element of the priority queue, `clear` to remove all elements in the priority queue and `size` to get the number of elements in the priority queue.
- A `Set` is a `Collection` that contains no duplicate elements. `HashSet` stores its elements in a hash table. `TreeSet` stores its elements in a tree.
- Interface `SortedSet` extends `Set` and represents a set that maintains its elements in sorted order. Class `TreeSet` implements `SortedSet`.
- `TreeSet` method `headSet` gets a view of a `treeSet` that is less than a specified element. Method `tailSet` gets a view that is greater than or equal to a specified element. Any changes made to the view are made to the `TreeSet`.

- `Map` map keys to values and cannot contain duplicate keys. `Map`s differ from `Set`s in that `Map`s contain both keys and values, whereas `Set`s contain only values. `HashMap`s store elements in a hash table, and `treeMap`s store elements in a tree.
  - `Hashtables` and `HashMap`s store elements in hash tables, and `treeMap`s store elements in trees.
  - `HashMap` is a generic class that takes two type arguments. The first type argument specifies the type of key, and the second type argument specifies the type of value.
  - `HashMap` method `put` adds a key and a value into a `HashMap`. Method `get` locates the value associated with the specified key. Method `isEmpty` determines whether the map is empty.
  - `HashMap` method `keySet` returns a set of the keys. `Map` methods `size` and `isEmpty` returns the number of key-value pairs in the `Map` and a boolean indicating whether the `Map` is empty, respectively.
  - Interface `SortedMap` extends `Map` and represents a map that maintains its keys in sorted order. Class `treeMap` implements `SortedMap`.
  - A `Properties` object is a persistent `Hashtable` object. Class `Properties` extends `Hashtable`.
  - The `Properties` no-argument constructor creates an empty `Properties` table with no default properties. There is also an overloaded constructor that is passed a reference to a default `Properties` object containing default property values.
  - `Properties` method `setProperty` specifies the value associated with the key argument. `Properties` method `getProperty` locates the value of the key specified as an argument. Method `store` saves the contents of the `Properties` object to the `OutputStream` object specified as the first argument. Method `load` restores the contents of the `Properties` object from the `InputStream` object specified as the argument.
- 

[Page 954]

- Collections from the collections framework are unsynchronized. Synchronization wrappers are provided for collections that can be accessed by multiple threads.
- The `Collections` API provides a set of `public static` methods for converting collections to unmodifiable versions. Unmodifiable wrappers throw `UnsupportedOperationException`s if attempts are made to modify the collection.
- The collections framework provides various abstract implementations of collection interfaces from which the programmer can quickly flesh out complete customized implementations.

## Self-Review Exercises

19.1 Fill in the blanks in each of the following statements:

- a. A(n) \_\_\_\_\_ is used to walk through a collection and can remove elements from the collection during the iteration.
- b. An element in a `List` can be accessed by using the element's \_\_\_\_\_.
- c. `Lists` are sometimes called \_\_\_\_\_.
- d. Java classes \_\_\_\_\_ and \_\_\_\_\_ provide the capabilities of array-like data structures that can resize themselves dynamically.
- e. If you do not specify a capacity increment, the system will \_\_\_\_\_ the size of the `Vector` each time additional capacity is needed.
- f. You can use a(n) \_\_\_\_\_ to create a collection that offers only read-only access to others while allowing readwrite access to yourself.
- g. \_\_\_\_\_ can be used to create stacks, queues, trees and deques (double-ended queues).
- h. Algorithm \_\_\_\_\_ of `Collections` determines whether two collections have elements in common.

19.2 Determine whether each statement is *true* or *false*. If *false*, explain why.

- a. Values of primitive types may be stored directly in a `Vector`.
- b. A `Set` can contain duplicate values.
- c. A `Map` can contain duplicate keys.
- d. A `LinkedList` can contain duplicate values.
- e. `Collections` is an `interface`.
- f. `Iterators` can remove elements.
- g. With hashing, as the load factor increases, the chance of collisions decreases.
- h. A `PriorityQueue` permits `null` elements.

## Answers to Self-Review Exercises

- 19.1 a) `Iterator`. b) `index`. c) `sequences`. d) `ArrayList`, `Vector`. e) `double`. f) `unmodifiable wrapper`.  
g) `LinkedLists`. h) `disjoint`.

---

[Page 956]

### 19.2

- a. False; a `Vector` stores only objects. Autoboxing occurs when adding a primitive type to the `Vector`, which means the primitive type is converted to its corresponding type-wrapper class.
- b. False. A `Set` cannot contain duplicate values.
- c. False. A `Map` cannot contain duplicate keys.
- d. True.
- e. False. `Collections` is a `class`; `Collection` is an `interface`.
- f. True.
- g. False. With hashing, as the load factor increases, there are fewer available slots relative to the total number of slots, so the chance of selecting an occupied slot (a collision) with a hashing operation increases.
- h. False. A `NullPointerException` is thrown if the program attempts to add `null` to a `PriorityQueue`.

## Exercises

19.3 Define each of the following terms:

- a. `Collection`
- b. `Collections`
- c. `Comparator`
- d. `List`
- e. load factor
- f. collision
- g. spacetime trade-off in hashing
- h. `HashMap`

19.4 Explain briefly the operation of each of the following methods of class `Vector`:

- a. `add`
- b. `insertElementAt`
- c. `set`
- d. `remove`
- e. `removeAllElements`
- f. `removeElementAt`
- g. `firstElement`
- h. `lastElement`
- i. `isEmpty`
- j. `contains`
- k. `indexOf`
- l. `size`
- m. `capacity`

19.5 Explain why inserting additional elements into a `Vector` object whose current size is less than its capacity is a relatively fast operation and why inserting additional elements into a `Vector` object whose current size is at capacity is a relatively slow operation.

19.6 By extending class `Vector`, Java's designers were able to create class `Stack` quickly. What are the negative aspects of this use of inheritance, particularly for class `Stack`?

19.7 Briefly answer the following questions:

- a. What is the primary difference between a `Set` and a `Map`?
  - b. Can a two-dimensional array be passed to `Arrays` method `asList`? If yes, how would an individual element be accessed?
  - c. What happens when you add a primitive type (e.g., `double`) value to a collection?
  - d. Can you print all the elements in a collection without using an `Iterator`? If yes, how?
- 

[Page 957]

19.8 Explain briefly the operation of each of the following `Iterator`-related methods:

- a. `iterator`
- b. `hasNext`
- c. `next`

19.9 Explain briefly the operation of each of the following methods of class `HashMap`:

- a. `put`
- b. `get`
- c. `isEmpty`
- d. `containsKey`
- e. `keySet`

19.10 Determine whether each of the following statements is *true* or *false*. If *false*, explain why.

- a. Elements in a `Collection` must be sorted in ascending order before a `binarySearch` may be performed.
- b. Method `first` gets the first element in a `treeSet`.
- c. A `List` created with `Arrays` method `asList` is resizable.
- d. Class `Arrays` provides `static` method `sort` for sorting array elements.

19.11 Explain the operation of each of the following methods of the `Properties` class:

- a. `load`
- b. `store`
- c. `getProperty`
- d. `list`

- 19.12 Rewrite lines 1726 in [Fig. 19.4](#) to be more concise by using the `asList` method and the `LinkedList` constructor that takes a `Collection` argument.
- 19.13 Write a program that reads in a series of first names and stores them in a `LinkedList`. Do not store duplicate names. Allow the user to search for a first name.
- 19.14 Modify the program of [Fig. 19.20](#) to count the number of occurrences of each letter rather than of each word. For example, the string "HELLO THERE" contains two `HS`, three `ES`, two `LS`, one `O`, one `T` and one `R`. Display the results.
- 19.15 Use a `HashMap` to create a reusable class for choosing one of the 13 predefined colors in class `Color`. The names of the colors should be used as keys, and the predefined `Color` objects should be used as values. Place this class in a package that can be imported into any Java program. Use your new class in an application that allows the user to select a color and draw a shape in that color.
- 19.16 Write a program that determines and prints the number of duplicate words in a sentence. Treat uppercase and lowercase letters the same. Ignore punctuation.
- 19.17 Rewrite your solution to [Exercise 17.8](#) to use a `LinkedList` collection.
- 19.18 Rewrite your solution to [Exercise 17.9](#) to use a `LinkedList` collection.
- 19.19 Write a program that takes a whole number input from a user and determines whether it is prime. If the number is not prime, display the unique prime factors of the number. Remember that a prime number's factors are only 1 and the prime number itself. Every number that is not prime has a unique prime factorization. For example, consider the number 54. The prime factors of 54 are 2, 3, 3 and 3. When the values are multiplied together, the result is 54. For the number 54, the prime factors output should be 2 and 3. Use `Sets` as part of your solution.
- 19.20 Write a program that uses a `StringTokenizer` to tokenize a line of text input by the user and places each token in a `treeSet`. Print the elements of the `treeSet`. [*Note:* This should cause the elements to be printed in ascending sorted order.]
- 19.21 The output of [Fig. 19.17](#) (`PriorityQueueTest`) shows that `PriorityQueue` orders `Double` elements in ascending order. Rewrite [Fig. 19.17](#) so that it orders `Double` elements in descending order (i.e., `9.8` should be the highest-priority element rather than `3.2`).

## OBJECTIVES

In this chapter you will learn:

- To differentiate between applets and applications.
- To observe some of Java's exciting capabilities through the JDK's demonstration applets.
- To write simple applets.
- To write a simple HyperText Markup Language (HTML) document to load an applet into an applet container and execute the applet.
- Five methods that are called automatically by an applet container during an applet's life cycle.

## 20.1. Introduction

[*Note:* This chapter and its exercises are intentionally small and simple for readers who wish to learn about applets after reading only the first few chapters of the book possibly just [Chapters 2](#) and [3](#). We present more complex applets in [Chapter 20](#), Multimedia: Applets and Applications, [Chapter 23](#), Multithreading and [Chapter 24](#), Networking.]

This chapter introduces [applets](#) Java programs that can be embedded in [HyperText Markup Language \(HTML\) documents](#) (i.e., Web pages). When a browser loads a Web page containing an applet, the applet downloads into the Web browser and executes.

The browser that executes an applet is generically known as the [applet container](#). The JDK includes the [appletviewer](#) applet container for testing applets as you develop them and before you embed them in Web pages. We typically demonstrate applets using the [appletviewer](#). If you would like to execute your applets in a Web browser, be aware that some Web browsers do not support J2SE 5.0 by default. You can visit [java.com](#) and click the **Get It Now** button to install the J2SE Runtime Environment (JRE) 5.0 for your browser. Several popular browsers are supported.

## 20.2. Sample Applets Provided with the JDK

Let's consider several demonstration applets provided with the JDK. Each sample applet comes with its source code. Some programmers find it interesting to read this source code to learn new and exciting Java features.

The demonstration programs provided with the JDK are located in a directory called **demo**. For Windows, the default location of the JDK 5.0's **demo** directory is

```
C:\Program Files\Java\jdk1.5.0\demo
```

On UNIX/Linux/Mac OS X, the default location is the directory in which you install the JDK followed by **jdk1.5.0/demo** for example,

```
/usr/local/jdk1.5.0/demo
```

For other platforms, there will be a similar directory (or folder) structure. This chapter assumes that the JDK is installed in **C:\Program Files\Java\jdk1.5.0\demo** on Windows or in your home directory in **~/jdk1.5.0** on UNIX/Linux/Mac OS X. You may need to update the locations specified here to reflect your chosen installation directory and disk drive, or a different version of the JDK.

If you are using a Java development tool that does not come with the Sun Java demos, you can download the JDK (with the demos) from the Sun Microsystems Java Web site

[java.sun.com/j2se/5.0/](http://java.sun.com/j2se/5.0/)

### TicTacToe Applet

The **TicTacToe** demonstration applet allows you to play Tic-Tac-Toe against the computer. To execute this applet, open a command window and change directories to the JDK's **demo** directory.

The **demo** directory contains several subdirectories. You can list them by issuing the **dir** command on Windows or the **ls** command on UNIX/Linux/Mac OS X. We discuss sample programs in the **applets** and **jfc** directories. The **applets** directory contains several demonstration applets. The **jfc** (Java Foundation Classes) directory contains applets and applications that demonstrate Java's graphics and GUI features.

Change directories to the **applets** directory and list its contents to see the directory names for the demonstration applets. [Figure 20.1](#) provides a brief description of each sample applet. If your browser supports J2SE 5.0, you can test these applets by opening the site [java.sun.com/j2se/5.0/docs/relnotes/demos.html](http://java.sun.com/j2se/5.0/docs/relnotes/demos.html) in your browser and clicking the link to each applet. We will demonstrate three of these applets by using the **appletviewer** command in a command window.

Figure 20.1. The examples from the **applets** directory.

| Example               | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Animator</b>       | Performs one of four separate animations.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ArcTest</b>        | Demonstrates drawing arcs. You can interact with the applet to change attributes of the arc that is displayed.                                                                                                                                                                                                                                                                                                          |
| <b>BarChart</b>       | Draws a simple bar chart.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Blink</b>          | Displays blinking text in different colors.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>CardTest</b>       | Demonstrates several GUI components and layouts.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Clock</b>          | Draws a clock with rotating hands, the current date and the current time. The clock updates once per second.                                                                                                                                                                                                                                                                                                            |
| <b>DitherTest</b>     | Demonstrates drawing with a graphics technique known as dithering that allows gradual transformation from one color to another.                                                                                                                                                                                                                                                                                         |
| <b>DrawTest</b>       | Allows the user mouse to draw lines and points in different colors by dragging the mouse.                                                                                                                                                                                                                                                                                                                               |
| <b>Fractal</b>        | Draws a fractal. Fractals typically require complex calculations to determine how they are displayed.                                                                                                                                                                                                                                                                                                                   |
| <b>GraphicsTest</b>   | Draws shapes to illustrate graphics capabilities.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>GraphLayout</b>    | Draws a graph consisting of many nodes (represented as rectangles) connected by lines. Drag a node to see the other nodes in the graph adjust on the screen and demonstrate complex graphical interactions.                                                                                                                                                                                                             |
| <b>ImageMap</b>       | Demonstrates an image with hot spots. Positioning the mouse pointer over certain areas of the image highlights the area and displays a message in the lower-left corner of the applet container window. Position over the mouth in the image to hear the applet say "hi."                                                                                                                                               |
| <b>JumpingBox</b>     | Moves a rectangle randomly around the screen. Try to catch it by clicking it with the mouse!                                                                                                                                                                                                                                                                                                                            |
| <b>MoleculeViewer</b> | Presents a three-dimensional view of several chemical molecules. Drag the mouse to view the molecule from different angles.                                                                                                                                                                                                                                                                                             |
| <b>NervousText</b>    | Draws text that jumps around the applet.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SimpleGraph</b>    | Draws a complex curve.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SortDemo</b>       | Compares three sorting techniques. Sorting (described in <a href="#">Chapter 16</a> ) arranges information in orderlike alphabetizing words. When you execute this example from a command window, three <b>appletviewer</b> windows appear. When you execute this example in a browser, the three demos appear side-by-side. Click in each demo to start the sort. Note that the sorts all operate at different speeds. |
| <b>SpreadSheet</b>    | Demonstrates a simple spreadsheet of rows and columns.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>TicTacToe</b>      | Allows the user to play Tic-Tac-Toe against the computer.                                                                                                                                                                                                                                                                                                                                                               |
| <b>WireFrame</b>      | Draws a three-dimensional shape as a wire frame. Drag the mouse to view the shape from different angles.                                                                                                                                                                                                                                                                                                                |

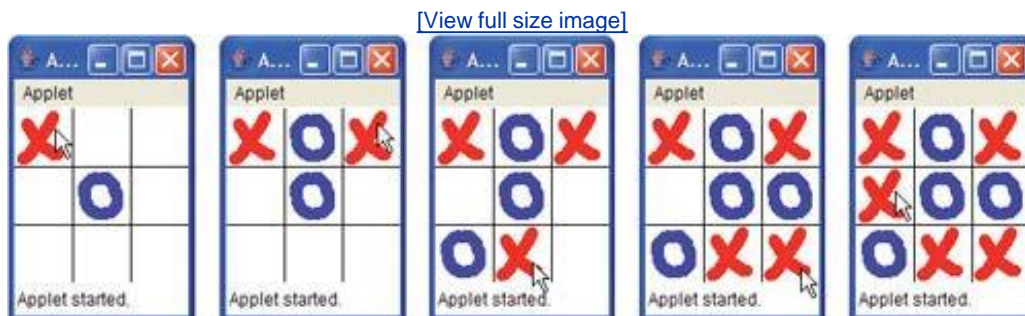

Change directories to subdirectory `TicTacToe`, where you will find the HTML document `example1.html` that is used to execute the applet. In the command window, type the command

```
appletviewer example1.html
```

and press *Enter*. This executes the `appletviewer` applet container, which loads the HTML document `example1.html` specified as its command-line argument. The `appletviewer` determines from the document which applet to load and executes the applet. [Figure 20.2](#) shows several screen captures of playing Tic-Tac-Toe with this applet.

Figure 20.2. TicTacToe applet sample execution.

(This item is displayed on page 962 in the print version)

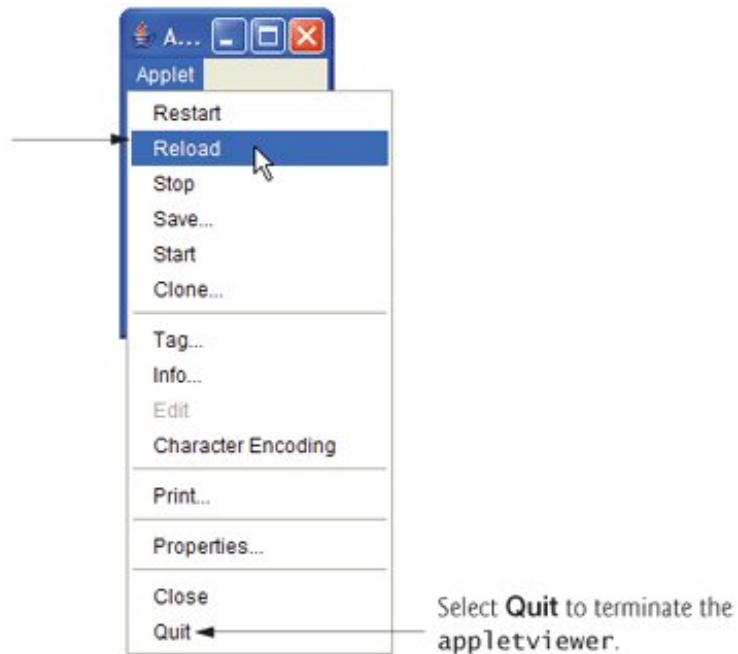

You are player X. To interact with the applet, point the mouse at the square where you want to place an X and click the mouse button. The applet plays a sound and places an X in the square if the square is open. If the square is occupied, this is an invalid move and the applet plays a different sound indicating that you cannot make the specified move. After you make a valid move, the applet responds by making its own move.

To play again, click the `appletviewer`'s **Applet menu** and select the **Reload menu item** ([Fig. 20.3](#)). To terminate the `appletviewer`, click the `appletviewer`'s **Applet menu** and select the **Quit menu item**.

Figure 20.3. **Applet menu** in the `appletviewer`.

[\[View full size image\]](#)

Reload the applet to execute it again.

## DrawTest Applet

The `DrawTest` applet allows you to draw lines and points in different colors. In the command window, change directories to directory `applets`, then to subdirectory `DrawTest`. You can move up the directory tree incrementally toward `demo` by issuing the command `"cd .."` in the command window. The `DrawTest` directory contains the `example1.html` document that is used to execute the applet. In the command window, type the command

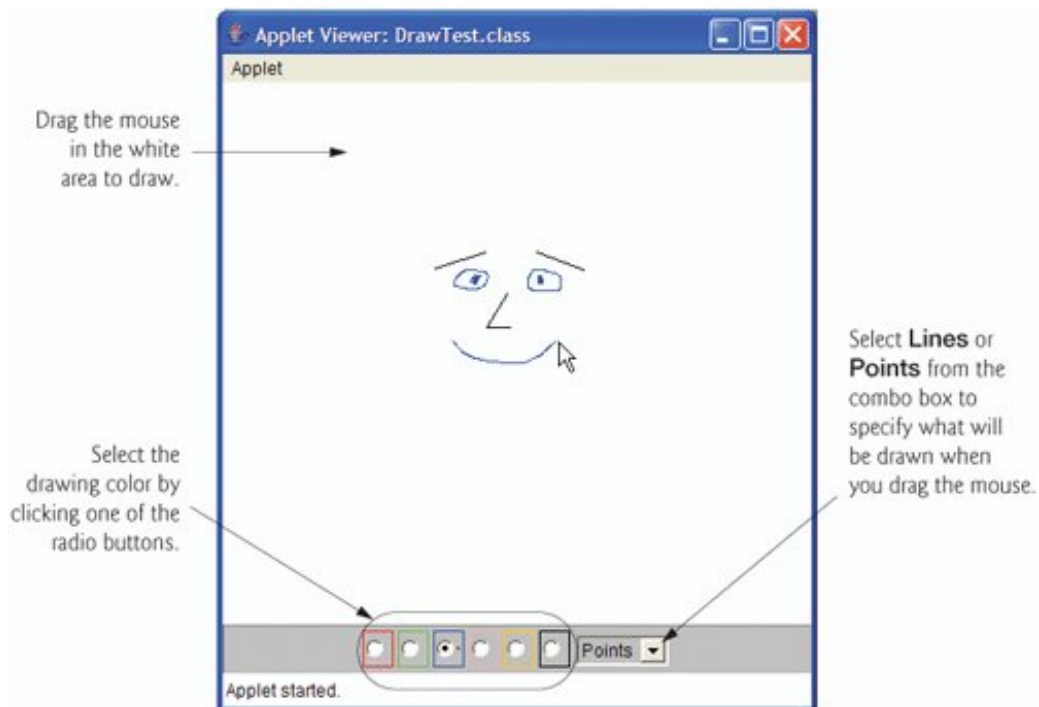

```
appletviewer example1.html
```

and press *Enter*. The `appletviewer` loads `example1.html`, determines from the document which applet to load and executes the applet. [Figure 20.4](#) shows a screen capture after some lines and points have been drawn.

Figure 20.4. DrawTest applet sample execution.

(This item is displayed on page 963 in the print version)

[\[View full size image\]](#)

By default the applet allows you to draw black lines by dragging the mouse across the applet. When you drag the mouse, note that the start point of the line always remains in the same place and the end point of the line follows the mouse pointer around the applet. The line is not permanent until you release the mouse button.

---

[Page 963]

Select a color by clicking one of the radio buttons at the bottom of the applet. You can select from red, green, blue, pink, orange and black. Change the shape to draw from Lines to Points by selecting Points from the combo box. To start a new drawing, select Reload from the `appletviewer`'s Applet menu.

## Java2D Applet

The `Java2D` applet demonstrates many features of the Java 2D API (which we introduced in [Chapter 12](#)). Change directories to the `jfc` directory in the JDK's `demo` directory, then change to the `Java2D` directory. In the command window, type the command

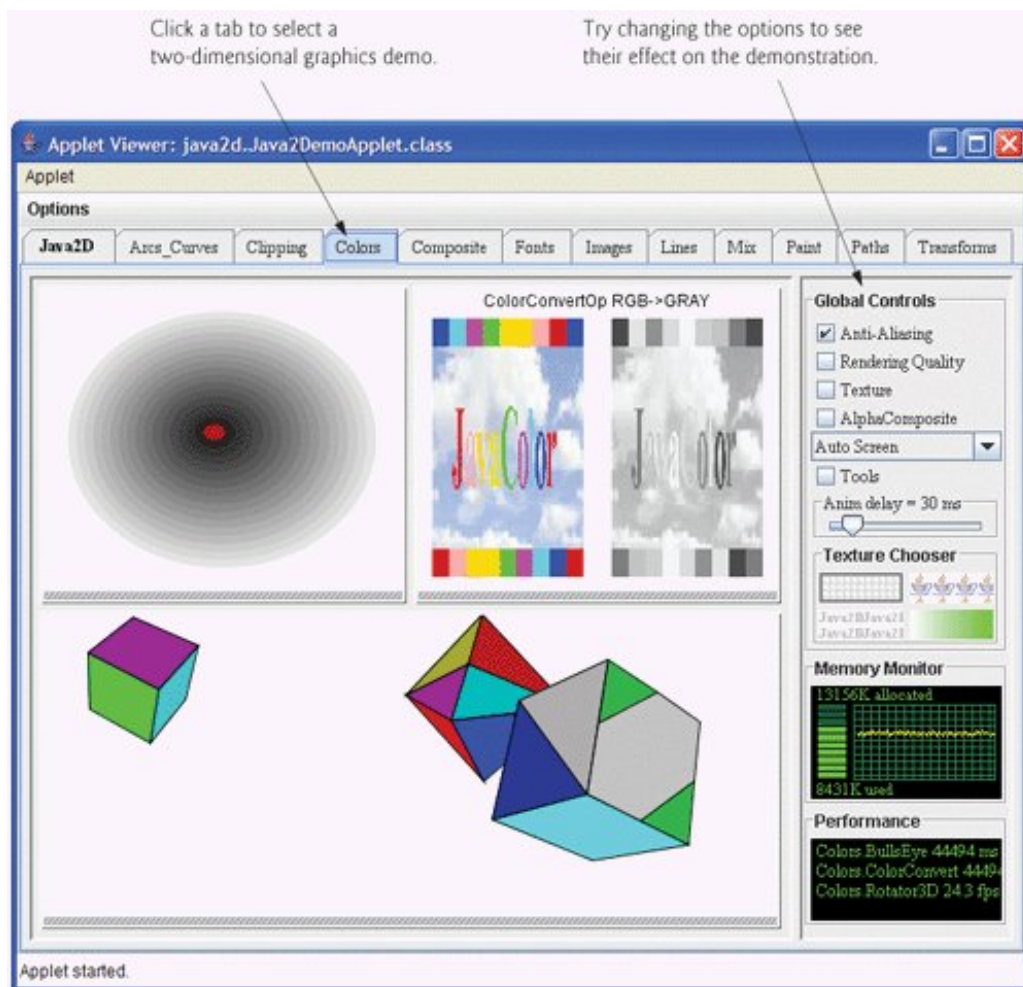

```
appletviewer Java2Demo.html
```

and press *Enter*. The `appletviewer` loads `Java2Demo.html`, determines from the document which applet to load and executes the applet. [Figure 20.5](#) shows a screen capture of one of this applet's many demonstrations of Java's two-dimensional graphics capabilities.

Figure 20.5. Java2D applet sample execution.

(This item is displayed on page 964 in the print version)

[\[View full size image\]](#)

At the top of the applet are tabs that look like file folders in a filing cabinet. This demo provides 12 tabs with Java 2D API features demonstrated on each tab. To change to a different part of the demo, simply click a different tab. Also, try changing the options in the upper-right corner of the applet. Some of these affect the speed with which the applet draws the graphics. For example, click the checkbox to the left of the word Anti-Aliasing to turn off anti-aliasing (a graphics technique for producing smoother on-screen graphics in which the edges of the graphic are blurred). When this feature is turned off, the animation speed increases for the animated shapes at the bottom of the demo ([Fig. 20.5](#)). This performance increase occurs because shapes that are not anti-aliased are less complex to draw.

## 20.3. Simple Java Applet: Drawing a String

Every Java applet is a graphical user interface on which you can place GUI components using the techniques introduced in [Chapter 11](#) or draw using the techniques demonstrated in [Chapter 12](#). In this chapter, we will demonstrate drawing on an applet. Examples in [Chapters 21](#), [23](#) and [24](#) demonstrate building an applet's graphical user interface.

Now let's build an applet of our own. We begin with a simple applet ([Fig. 20.6](#)) that draws "Welcome to Java Programming!" on the applet. [Figure 20.7](#) shows this applet executing in two applet containers: the `appletviewer` and the Microsoft Internet Explorer Web browser. At the end of this section, you will learn how to execute the applet in a Web browser.

Figure 20.6. Applet that draws a string.

(This item is displayed on page 965 in the print version)

```
1 // Fig. 20.6: WelcomeApplet.java
2 // A first applet in Java.
3 import java.awt.Graphics; // program uses class Graphics
4 import javax.swing.JApplet; // program uses class JApplet
5
6 public class WelcomeApplet extends JApplet
7 {
8 // draw text on applet's background
9 public void paint(Graphics g)
10 {
11 // call superclass version of method paint
12 super.paint(g);
13
14 // draw a String at x-coordinate 25 and y-coordinate 25
15 g.drawString("Welcome to Java Programming!", 25, 25);
16 } // end method paint
17 } // end class WelcomeApplet
```

Figure 20.7. Sample outputs of the `WelcomeApplet` in [Fig. 20.6](#).

(This item is displayed on page 965 in the print version)

[\[View full size image\]](#)

## Creating the Applet Class

Line 3 imports class `Graphics` to enable the applet to draw graphics, such as lines, rectangles, ovals and strings of characters. Class `JApplet` (imported at line 4) from package `javax.swing` is used to create applets. As with applications, every Java applet contains at least one `public` class declaration. An applet container can create only objects of classes that are `public` and extend `JApplet` (or the `Applet` class from early versions of Java). For this reason, class `WelcomeApplet` (lines 617) extends `JApplet`.

---

[Page 965]

---

[Page 966]

---

An applet container expects every Java applet to have methods named `init`, `start`, `paint`, `stop` and `destroy`, each of which is declared in class `JApplet`. Each new applet class you create inherits default implementations of these methods from class `JApplet`. These methods can be overridden (redefined) to perform tasks that are specific to your applet. [Section 20.4](#) discusses each of these methods in more detail.

When an applet container loads class `WelcomeApplet`, the container creates an object of type `WelcomeApplet`, then calls three of the applet's methods. In sequence, these three methods are `init`, `start` and `paint`. If you do not declare these methods in your applet, the applet container calls the inherited versions. The superclass methods `init` and `start` have empty bodies, so they do not perform any tasks. The superclass method `paint` does not draw anything on the applet.

You might wonder why it is necessary to inherit methods `init`, `start` and `paint` if their default implementations do not perform tasks. Some applets do not use all three of these methods. However, the applet container does not know that. Thus, it expects every applet to have these methods, so that it can provide a consistent start-up sequence for each applet. This is similar to applications' always starting execution with `main`. Inheriting the "default" versions of these methods guarantees that the applet container can execute each applet uniformly. Also, inheriting default implementations of these methods allows the programmer to concentrate on defining only the methods required for a particular applet.

## Overriding Method `paint` for Drawing

To enable our applet to draw, class `WelcomeApplet` overrides method `paint` (lines 916) by placing statements in the body of `paint` that draw a message on the screen. Method `paint` receives a parameter of type `Graphics` (called `g` by convention), which is used to draw graphics on the applet. You do not call method `paint` explicitly in an applet. Rather, the applet container calls `paint` to tell the applet when to draw, and the applet container is responsible for passing a `Graphics` object as an argument.

Line 12 calls the superclass version of method `paint` that was inherited from `JApplet`. This statement should be the first statement in every applet's `paint` method. Omitting it can cause subtle drawing errors in applets that combine drawing and GUI components.

Line 15 uses `Graphics` method `drawString` to draw `Welcome to Java Programming!` on the applet. The method receives as arguments the `String` to draw and the  $x$ - $y$  coordinates at which the bottom-left corner of the `String` should appear in the drawing area. When line 15 executes, it draws the `String` on the applet at the coordinates 25 and 25.

### 20.3.1. Executing an Applet in the `appletviewer`

As with application classes, you must compile an applet class before it can execute. After creating class `WelcomeApplet` and saving it in the file `WelcomeApplet.java`, open a command window, change to the directory in which you saved the applet class declaration and compile class `WelcomeApplet`.

Recall that applets are embedded in Web pages for execution in an applet container (`appletviewer` or a browser). Before you can execute the applet, you must create an HTML (HyperText Markup Language) document that specifies which applet to execute in the applet container. Typically, an HTML document ends with an `.html` or `.htm` file-name extension. [Figure 20.8](#) shows a simple HTML document `WelcomeApplet.html` that loads the applet defined in [Fig. 20.6](#) into an applet container. [Note: If you are interested in learning more about HTML, the CD that accompanies this book contains three chapters from our book *Internet and World Wide Web How to Program, Third Edition* that introduce the current version of HTML (known as XHTML) and the Web page formatting capability known as Cascading Style Sheets (CSS).]

---

[Page 967]

Figure 20.8. `WelcomeApplet.html` loads `WelcomeApplet` ([Fig. 20.6](#)) into an applet container.

```
1 <html>
2 <applet code = "WelcomeApplet.class" width = "300" height = "45">
3 </applet>
4 </html>
```

Most HTML elements are delimited by pairs of `tags`. For example, lines 1 and 4 of [Fig. 20.8](#) indicate the beginning and the end, respectively, of the HTML document. All HTML tags begin with a left angle bracket, `<`, and end with a right angle bracket, `>`. Lines 23 specify an `applet element` that tells the applet container to load a specific applet and defines the size of the applet's display area (its width and height in pixels) in the applet container. Normally, the applet and its corresponding HTML document are stored in the same directory on disk. Typically, a browser loads an HTML document from a computer (other than your own) connected to the Internet. However, HTML documents also can reside on your computer (as you saw in [Section 20.2](#)). When an applet container encounters an HTML document that contains an applet, the applet container automatically loads the applet's `.class` file (or files) from the same directory on the computer in which the HTML document resides.

The `applet` element has several `attributes`. The first attribute in line 2, `code = "WelcomeApplet.class"`,

indicates that the file `WelcomeApplet.class` contains the compiled applet class. The second and third attributes in line 2 indicate the `width` (300) and the `height` (45) of the applet in pixels. The `</applet>` tag (line 3) terminates the `applet` element that began at line 2. The `</html>` tag (line 4) terminates the HTML document.

## Look-and-Feel Observation 20.1

*To ensure that it can be viewed properly on most computer screens, an applet should generally be less than 1024 pixels wide and 768 pixels tall dimensions supported by most computer screens.*

## Common Programming Error 20.1

*Forgetting the ending `</applet>` tag prevents the applet from executing in some applet containers. The `appletviewer` terminates without indicating an error. Some Web browsers simply ignore the incomplete `applet` element.*

## Error-Prevention Tip 20.1

*If you receive a `MissingResourceException` error message when loading an applet into the `appletviewer` or a browser, check the `<applet>` tag in the HTML document carefully for syntax errors, such as commas (,) between the attributes.*

The `appletviewer` understands only the `<applet>` and `</applet>` HTML tags and ignores all other tags in the document. The `appletviewer` is an ideal place to test an applet and ensure that it executes properly. Once the applet's execution is verified, you can add its HTML tags to a Web page that others can view in their Web browsers.

To execute `WelcomeApplet` in the `appletviewer`, open a command window, change to the directory containing your applet and HTML document, then type

```
appletviewer WelcomeApplet.html
```

## Error-Prevention Tip 20.2

*Test your applets in the `appletviewer` applet container before executing them in a Web browser. Browsers often save a copy of an applet in memory until all the browser's windows are closed. If you change an applet, recompile it, then reload it in your browser, the browser may still execute the original version of the applet. Close all your browser windows to remove the old applet from memory. Open a new browser window and load the applet to see your changes.*

### Error-Prevention Tip 20.3

*Test your applets in every Web browser in which they will execute to ensure that they operate correctly.*

## 20.3.2. Executing an Applet in a Web Browser

The sample program executions in [Fig. 20.6](#) demonstrate `WelcomeApplet` executing in the `appletviewer` and in Microsoft Internet Explorer Web browser. To execute an applet in Internet Explorer, perform the following steps:

1. Select Open... from the File menu.
2. In the dialog box that appears, click the Browse... button.
3. In the dialog box that appears, locate the directory containing the HTML document for the applet you wish to execute.
4. Select the HTML document.
5. Click the Open button.
6. Click the OK button.

[*Note:* The steps for executing applets in other Web browsers are similar.]

If your applet executes in the `appletviewer`, but does not execute in your Web browser, Java may not be installed and configured for your browser. In this case, visit the Web site [java.com](http://java.com) and click the Get It Now button to install Java for your browser. In Internet Explorer, if this does not fix the problem, you might need to manually configure Internet Explorer to use J2SE 5.0. To do so, click the Tools menu and select Internet Options..., then click the Advanced tab in the window that appears. Locate the option "Use JRE v1.5.0 for <applet> (requires restart)" and ensure that it is checked, then click OK. Close all your browser windows before attempting to execute another applet in the browser.

## 20.4. Applet Life-Cycle Methods

Now that you have created an applet, let's consider the five applet methods that are called by the applet container from the time the applet is loaded into the browser to the time that the applet is terminated by the browser. These methods correspond to various aspects of an applet's life cycle. [Figure 20.9](#) lists these methods, which are inherited into your applet classes from class `JApplet`. The table specifies when each method gets called and explains its purpose. Other than method `paint`, these methods have empty bodies by default. If you would like to declare any of these methods in your applets and have the applet container call them, you must use the method headers shown in [Fig. 20.9](#). If you modify the method headers (e.g., by changing the method names or by providing additional parameters), the applet container will not call your methods. Instead, it will call the superclass methods inherited from `JApplet`.

[Page 969]

Figure 20.9. `JApplet` life cycle methods that are called by an applet container during an applet's execution.

| Method                                       | When the method is called and its purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>public void init()</code>              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                              | Called once by the applet container when an applet is loaded for execution. This method initializes an applet. Typical actions performed here are initializing fields, creating GUI components, loading sounds to play, loading images to display (see <a href="#">Chapter 20</a> , Multimedia: Applets and Applications) and creating threads (see <a href="#">Chapter 23</a> , Multithreading).                                                                                                                                                                                   |
| <code>public void start()</code>             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                              | Called by the applet container after method <code>init</code> completes execution. In addition, if the user browses to another Web site and later returns to the applet's HTML page, method <code>start</code> is called again. The method performs any tasks that must be completed when the applet is loaded for the first time and that must be performed every time the applet's HTML page is revisited. Actions performed here might include starting an animation (see <a href="#">Chapter 21</a> ) or starting other threads of execution (see <a href="#">Chapter 23</a> ). |
| <code>public void paint( Graphics g )</code> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                              | Called by the applet container after methods <code>init</code> and <code>start</code> . Method <code>paint</code> is also called when the applet needs to be repainted. For example, if the user covers the applet with another open window on the screen and later uncovers the applet, the <code>paint</code> method is called. Typical actions performed here involve drawing with the <code>Graphics</code> object <code>g</code> that is passed to the <code>paint</code> method by the applet container.                                                                      |
| <code>public void stop()</code>              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                              | This method is called by the applet container when the user leaves the applet's Web page by browsing to another Web page. Since it is possible that the user might return to the Web page containing the applet, method <code>stop</code> performs tasks that might be required to suspend the applet's execution, so that the applet does not use computer processing time when it is not displayed on the screen. Typical actions performed here would stop the execution of animations and threads.                                                                              |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Method                             | When the method is called and its purpose                                                                                                                                                                                                                                                                                                                                       |
| <code>public void destroy()</code> |                                                                                                                                                                                                                                                                                                                                                                                 |
|                                    | This method is called by the applet container when the applet is being removed from memory. This occurs when the user exits the browsing session by closing all the browser windows and may also occur at the browser's discretion when the user has browsed to other Web pages. The method performs any tasks that are required to clean up resources allocated to the applet. |

---

[Page 970]

## Common Programming Error 20.2

*Declaring methods `init`, `start`, `paint`, `stop` or `destroy` with method headers that differ from those shown in [Figure 20.9](#) results in methods that will not be called by the applet container. The code specified in your versions of the methods will not execute.*

## 20.5. Initializing an Instance Variable with Method `init`

Our next applet ([Fig. 20.10](#)) computes the sum of two values input by the user and displays the result by drawing a `String` inside a rectangle on the applet. The sum is stored in an instance variable of class `AdditionApplet`, so it can be used in both method `init` and method `paint`. The HTML document to load this applet into the `appletviewer` is shown in [Fig. 20.11](#).

Figure 20.10. Adding `double` values.

(This item is displayed on pages 970 - 971 in the print version)

```
1 // Fig. 20.10: AdditionApplet.java
2 // Adding two floating-point numbers.
3 import java.awt.Graphics; // program uses class Graphics
4 import javax.swing.JApplet; // program uses class JApplet
5 import javax.swing.JOptionPane; // program uses class JOptionPane
6
7 public class AdditionApplet extends JApplet
8 {
9 private double sum; // sum of values entered by user
10
11 // initialize applet by obtaining values from user
12 public void init ()
13 {
14 String firstNumber; // first string entered by user
15 String secondNumber; // second string entered by user
16
17 double number1; // first number to add
18 double number2; // second number to add
19
20 // obtain first number from user
21 firstNumber = JOptionPane.showInputDialog(
22 "Enter first floating-point value");
23
24 // obtain second number from user
25 secondNumber = JOptionPane.showInputDialog(
26 "Enter second floating-point value");
27
28 // convert numbers from type String to type double
29 number1 = Double.parseDouble(firstNumber);
30 number2 = Double.parseDouble(secondNumber);
31
32 sum = number1 + number2; // add numbers
33 } // end method init
34
35 // draw results in a rectangle on applet's background
36 public void paint(Graphics g)
37 {
38 super.paint(g); // call superclass version of method paint
39
40 // draw rectangle starting from (15, 10) that is 270
41 // pixels wide and 20 pixels tall
```

```

42 g.drawRect(15, 10, 270, 20);
43
44 // draw results as a String at (25, 25)
45 g.drawString("The sum is " + sum, 25, 25);
46 } // end method paint
47 } // end class AdditionApplet

```

[\[View full size image\]](#)

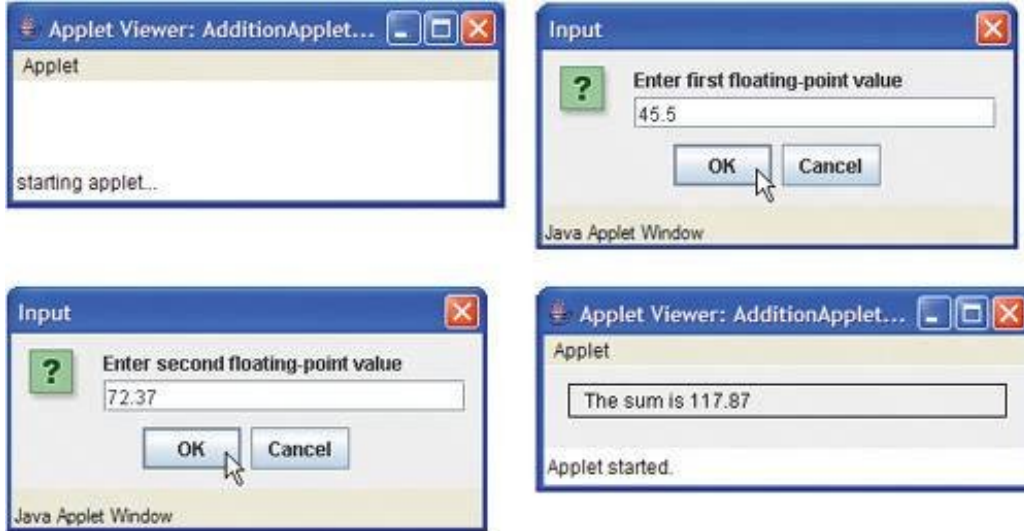

Figure 20.11. **AdditionApplet.html** loads class **AdditionApplet** of [Fig. 20.10](#) into an applet container.

(This item is displayed on page 971 in the print version)

```

1 <html>
2 <applet code = "AdditionApplet.class" width = "300" height = "65">
3 </applet>
4 </html>

```

The applet requests that the user enter two floating-point numbers. Line 9 ([Fig. 20.10](#)) declares instance variable `sum` of type `double`. The applet contains two methods `init` (lines 1233) and `paint` (lines 3646). When an applet container loads this applet, the container creates an instance of class `AdditionApplet` and calls its `init` method; this occurs only once during an applet's execution. Method `init` normally initializes the applet's fields (if they need to be initialized to values other than their defaults) and performs other tasks that should occur only once when the applet begins execution. The first line of `init` always appears as shown in line 12, which indicates that `init` is a `public` method that receives no arguments and returns no information when it completes.

Lines 1430 declare variables to store the values entered by the user, obtain the user input and convert the `Strings` entered by the user to `double` values by using `Double` method `parseDouble`.

The assignment statement at line 32 sums the values stored in variables `number1` and `number2`, and assigns the result to instance variable `sum`. At this point, the applet's `init` method returns program control to the applet container, which then calls the applet's `start` method. We did not declare `start` in this applet, so the one inherited from class `JApplet` is called here. You will see typical uses of method `start` in [Chapters 21](#) and [23](#).

Next, the applet container calls the applet's `paint` method. In this example, method `paint` draws a rectangle (line 42) in which the result of the addition will appear. Line 45 calls the `Graphics` object's `drawString` method to display the results. The statement concatenates the value of instance variable `sum` to the `String` "The sum is" and displays the concatenated `String`.

## Software Engineering Observation 20.1

*The only statements that should be placed in an applet's `init` method are those that should execute only once when the applet is initialized.*

## 20.6. Sandbox Security Model

It would be dangerous to allow applets, which are typically downloaded from the Internet, to read and write files on a client computer or access other system resources. For example, what would happen if you downloaded a malicious applet? The Java platform uses the [sandbox security model](#) to prevent code that is downloaded to your local computer from accessing local system resources, such as files. Code executing in the "sandbox" is not allowed to "play outside the sandbox." For information on security and applets, visit

[developer.java.sun.com/developer/technicalArticles/Security/Signed](http://developer.java.sun.com/developer/technicalArticles/Security/Signed)

For information on the Java 2 Platform security model, visit

[java.sun.com/j2se/5.0/docs/guide/security/spec/security-spec.doc1.html](http://java.sun.com/j2se/5.0/docs/guide/security/spec/security-spec.doc1.html)

## 20.7. Internet and Web Resources

If you have access to the Internet, a large number of Java applet resources are available to you. The best place to start is at the source the Sun Microsystems Java Web site, [java.sun.com](http://java.sun.com). The Web page

[java.sun.com/applets](http://java.sun.com/applets)

contains several Java applet resources, including free applets that you can use on your own Web site, the demonstration applets from the JDK and other applets (many of which you can download). In a section entitled "Applets at Work," you can read about the uses of applets in industry.

If you do not have Java installed and configured for your browser, you can visit

[java.com](http://java.com)

and click the Get It Now button to download and install Java in your browser. Instructions are provided for various versions of Windows, Linux, Solaris and Mac OS.

The Sun Microsystems Java Web site

[java.sun.com](http://java.sun.com)

includes technical support, discussion forums, technical articles, resources, announcements of new Java features and early access to new Java technologies.

For various free online tutorials, visit the site

[java.sun.com/learning](http://java.sun.com/learning)

Another useful Web site is [JARS](http://www.jars.com) Originally called the [Java Applet Rating Service](http://www.jars.com). The JARS site

[www.jars.com](http://www.jars.com)

originally was a large Java repository for applets. It rated every applet registered at the site as top 1%, top 5% or top 25%, so you could view the best applets on the Web. Early in the development of the Java language, having your applet rated here was a great way to demonstrate your Java programming abilities. JARS is now an all-around resource for Java programmers.

The resources listed in this section provide hyperlinks to many other Java-related Web sites. If you have Internet access, spend some time browsing these sites, executing applets and reading the source code for the applets when it is available. This will help you to rapidly expand your Java knowledge.

## 20.8. Wrap-Up

In this chapter, you learned the fundamentals of Java applets. You learned basic HTML concepts that allowed you to embed an applet in a Web page and execute the applet in an applet container such as the `appletviewer` or a Web browser. In addition, you learned the five methods that are called automatically by the applet container during an applet's life cycle. In the next chapter, you will see several additional applets as we present basic multimedia capabilities. In [Chapter 23](#), Multithreading, you will see an applet with `start` and `stop` methods that are used to control multiple threads of execution. In [Chapter 24](#), Networking, we demonstrate how to customize an applet via parameters that are specified in an `applet` HTML element.

## Summary

- Applets are Java programs that can be embedded in HyperText Markup Language (HTML) documents.
  - When a browser loads a Web page containing an applet, the applet downloads into the Web browser and executes.
  - The browser that executes an applet is generically known as the applet container. The JDK includes the `appletviewer` applet container for testing applets before you embed them in a Web page.
  - To reexecute an applet in the `appletviewer`, click the `appletviewer`'s Applet menu and select the Reload menu item.
  - To terminate the `appletviewer`, select Quit from the `appletviewer`'s Applet menu.
- 

- Every Java applet is a graphical user interface on which you can place GUI components or draw.
- Class `JApplet` from package `javax.swing` is used to create applets.
- An applet container can create only objects of classes that are `public` and extend `JApplet` (or the `Applet` class from early versions of Java).
- An applet container expects every Java applet to have methods named `init`, `start`, `paint`, `stop` and `destroy`, each of which is declared in class `JApplet`. Each new applet class you create inherits default implementations of these methods from class `JApplet`.
- When an applet container loads an applet, the container creates an object of the applet's type, then calls the applet's `init`, `start` and `paint` methods. If you do not declare these methods in your applet, the applet container calls the inherited versions.
- The superclass methods `init` and `start` have empty bodies, so they do not perform any tasks. The superclass method `paint` does not draw anything on the applet.
- To enable an applet to draw, override its method `paint`. You do not call method `paint` explicitly in an applet. Rather, the applet container calls `paint` to tell the applet when to draw, and the applet container is responsible for passing a `Graphics` object as an argument.
- The first statement in method `paint` should be a call to the superclass version of method `paint`. Omitting this can cause subtle drawing errors in applets that combine drawing and GUI components.
- Before you can execute an applet, you must create an HTML (HyperText Markup Language) document that specifies which applet to execute in the applet container. Typically, an HTML document ends with an `".html"` or `".htm"` file-name extension.
- Most HTML elements are delimited by pairs of `tags`. All HTML tags begin with a left angle bracket, `<`, and end with a right angle bracket, `>`.
- An `applet` element tells the applet container to load a specific applet and defines the size of the applet's display area (its width and height in pixels) in the applet container.
- Normally, an applet and its corresponding HTML document are stored in the same directory.
- Typically, a browser loads an HTML document from a computer (other than your own) connected to the Internet.

- When an applet container encounters an HTML document that contains an applet, the applet container automatically loads the applet's `.class` file(s) from the same directory on the computer in which the HTML document resides.
  - The `appletviewer` understands only the `<applet>` and `</applet>` HTML tags and ignores all other tags in the document.
  - The `appletviewer` is an ideal place to test an applet and ensure that it executes properly. Once the applet's execution is verified, you can add its HTML tags to a Web page that others can view in their Web browsers.
  - There are five applet methods that are called by the applet container from the time the applet is loaded into the browser to the time that the applet is terminated by the browser. These methods correspond to various aspects of an applet's life cycle.
  - Method `init` is called once by the applet container when an applet is loaded for execution. This method initializes the applet.
  - Method `start` is called by the applet container after method `init` completes execution. In addition, if the user browses to another Web site and later returns to the applet's HTML page, method `start` is called again.
  - Method `paint` is called by the applet container after methods `init` and `start`. Method `paint` is also called when the applet needs to be repainted.
- 

[Page 975]

- Method `stop` is called by the applet container when the user leaves the applet's Web page by browsing to another Web page.
- Method `destroy` is called by the applet container when the applet is being removed from memory. This occurs when the user exits the browsing session by closing all the browser windows and may also occur at the browser's discretion when the user has browsed to other Web pages.

## Self-Review Exercises

20.1 Fill in the blanks in each of the following:

- a. Java applets begin execution with a series of three method calls: \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.
- b. The \_\_\_\_\_ method is invoked for an applet each time the user of a browser leaves an HTML page on which the applet resides.
- c. Every applet should extend class \_\_\_\_\_.
- d. The \_\_\_\_\_ or a browser can be used to execute a Java applet.
- e. The \_\_\_\_\_ method is called each time the user of a browser revisits the HTML page on which an applet resides.
- f. To load an applet into a browser, you must first define a(n) \_\_\_\_\_ file.
- g. The \_\_\_\_\_ method is called once when an applet begins execution.
- h. The \_\_\_\_\_ method is invoked to draw on an applet.
- i. The \_\_\_\_\_ method is invoked for an applet when the browser removes it from memory.
- j. The \_\_\_\_\_ and \_\_\_\_\_ HTML tags specify that an applet should be loaded into an applet container and executed.

## Answers to Self-Review Exercises

20.1 a) `init`, `start`, `paint`. b) `stop`. c) `JApplet` (or `Applet`). d) `appletviewer`. e) `start`. f) `HTML`. g) `init`. h) `paint`. i) `destroy`. j) `<applet>`, `</applet>`.

## Exercises

- 20.2 Write an applet that asks the user to enter two floating-point numbers, obtains the two numbers from the user and draws their sum, product (multiplication), difference and quotient (division). Use the techniques shown in [Fig. 20.10](#).

---

 [Page 976]

- 20.3 Write an applet that asks the user to enter two floating-point numbers, obtains the numbers from the user and displays the two numbers first and then the larger number followed by the words "is larger" as a string on the applet. If the numbers are equal, the applet should print the message "These numbers are equal". Use the techniques shown in [Fig. 20.10](#).
- 20.4 Write an applet that inputs three floating-point numbers from the user and displays the sum, average, product, smallest and largest of these numbers as strings on the applet. Use the techniques shown in [Fig. 20.10](#).
- 20.5 Write an applet that asks the user to input the radius of a circle as a floating-point number and draws the circle's diameter, circumference and area. Use the value 3.14159 for  $\pi$ . Use the techniques shown in [Fig. 20.10](#). [Note: You may also use the predefined constant `Math.PI` for the value of  $\pi$ . This constant is more precise than the value 3.14159. Class `Math` is defined in the `java.lang` package, so you do not need to `import it`.] Use the following formulas ( $r$  is the radius):

$$\begin{aligned} \text{diameter} &= 2r \\ \text{circumference} &= 2\pi r \\ \text{area} &= \pi r^2 \end{aligned}$$

- 20.6 Write an applet that reads five integers, determines which are the largest and smallest integers in the group and prints them. Use only the programming techniques you learned in this chapter and [Chapter 2](#). Draw the results on the applet.
- 20.7 Write an applet that draws a checkerboard pattern as follows:

- 20.8 Write an applet that draws rectangles of different sizes and locations.
- 20.9 Write an applet that allows the user to input values for the arguments required by method `drawRect`, then draws a rectangle using the four input values.

- 20.10 Class `Graphics` contains method `drawOval`, which takes as arguments the same four arguments as method `drawRect`. The arguments for method `drawOval` specify the "bounding box for the oval" the sides of the bounding box are the boundaries of the oval. Write a Java applet that draws an oval and a rectangle with the same four arguments. The oval will touch the rectangle at the center of each side.
- 20.11 Modify the solution to [Exercise 20.10](#) to output ovals of different shapes and sizes.
- 20.12 Write an applet that allows the user to input the four arguments required by method `drawOval`, then draws an oval using the four input values.

## OBJECTIVES

In this chapter you will learn:

- How to get and display images.
- To create animations from sequences of images.
- To create image maps.
- To get, play, loop and stop sounds, using an **AudioClip**.
- To play video using interface **Player**.

**NEXT** 

## 21.1. Introduction

Welcome to what may be the largest revolution in the history of the computer industry. Those who entered the field decades ago were interested in using computers primarily to perform arithmetic calculations at high speed. As the computer field evolved, we began to realize that the data-manipulation capabilities of computers are equally important. The "sizzle" of Java is **multimedia** the use of **sound**, **images**, graphics and **video** to make applications "come alive." Although most multimedia in Java applications is two-dimensional, Java programmers already can use the **Java 3D API** to create substantial 3D graphics applications (Sun provides an online tutorial for the Java 3D API at [java.sun.com/developer/onlineTraining/java3d](http://java.sun.com/developer/onlineTraining/java3d)).

Multimedia programming offers many new challenges. The field is already enormous and is growing rapidly. People are rushing to equip their computers for multimedia. Most new computers sold today are "multimedia ready," with CD-RW and DVD drives, audio boards and special video capabilities. Economical desktop and laptop computers are so powerful that they can store and play DVD-quality sound and video, and we expect to see further advances in the kinds of programmable multimedia capabilities available through programming languages. One thing that we have learned is to plan for the "impossible" in the computer and communications fields, the "impossible" has repeatedly become reality.

Among users who want graphics, many now want three-dimensional, high-resolution, color graphics. True three-dimensional imaging may become available within the next decade. Imagine having high-resolution, "theater-in-the-round," three-dimensional television. Sporting and entertainment events will seem to take place on your living room floor! Medical students worldwide will see operations being performed thousands of miles away, as if they were occurring in the same room. People will be able to learn how to drive with extremely realistic driving simulators in their homes before they get behind the wheel. The possibilities are exciting and endless.

Multimedia demands extraordinary computing power. Until recently, affordable computers with that kind of power were not available. Today's ultrapowerful processors, like the SPARC Ultra 5 from Sun Microsystems, the Pentium and Itanium 2 from Intel, the PowerPC G5 from IBM and Apple, and the processors from MIPS/Silicon Graphics (among others) make effective multimedia possible. The computer and communications industries will be primary beneficiaries of the multimedia revolution. Users will be willing to pay for the faster processors, larger memories and wider communications bandwidths that support demanding multimedia applications. Ironically, users may not have to pay more, because the fierce competition in these industries has historically driven prices down.

---

[Page 979]

We need programming languages that make creating multimedia applications easy. Most programming languages do not incorporate such capabilities. However, Java, through its class libraries, provides extensive multimedia facilities that enable you to start developing powerful multimedia applications immediately.

This chapter presents several examples of interesting multimedia features that you will need to build useful applications, including:

1. the basics of manipulating images.
2. creating smooth animations.
3. playing audio files with the **AudioClip** interface.
4. creating image maps that can sense when the cursor is over them, even without a mouse click.

5. playing video files using the `Player` interface.

The exercises for this chapter suggest dozens of challenging and interesting projects. When we were creating these exercises, the ideas just kept flowing. Multimedia leverages creativity in ways that we did not experience with "conventional" computer capabilities. [*Note:* Java's multimedia capabilities go far beyond those presented in this chapter. They include the [Java Media Framework \(JMF\) API](#) (for adding audio and video media to an application), [Java Sound API](#) (for playing, recording and modifying audio), Java 3D API (for creating and modifying 3D graphics), [Java Advanced Imaging API](#) (for image-processing capabilities, such as cropping and scaling), [Java Speech API](#) (for inputting voice commands from the user or outputting voice commands to the user), Java 2D API (for creating and modifying 2D graphics, covered in [Chapter 12](#)) and [Java Image I/O API](#) (for reading from and outputting images to files). [Section 21.8](#) provides Web links for each of these APIs.]

## 21.2. Loading, Displaying and Scaling Images

Java's multimedia capabilities include graphics, images, animations, sounds and video. We begin our discussion with images. We will use a few different images in this chapter. Developers can create such images with any image software, such as Adobe® Photoshop™, Jasc® Paint Shop Pro™ or Microsoft® Paint.

The applet of [Fig. 21.1](#) demonstrates loading an `Image` (package `java.awt`) and loading an `ImageIcon` (package `javax.swing`). Both classes are used to load and display images. The applet displays the `Image` in its original size and scaled to a larger size, using two versions of `Graphics` method `drawImage`. The applet also draws the `ImageIcon`, using the icon's method `paintIcon`. Class `ImageIcon` implements interface `Serializable`, which allows `ImageIcon` objects to be easily written to a file or sent across the Internet. Class `ImageIcon` is also easier to use than `Image`, because its constructor can receive arguments of several different formats, including a byte array containing the bytes of an image, an `Image` already loaded in memory, and a `String` or a `URL` object, which both can be used to represent the location of the image. A `URL` object represents a Uniform Resource Locator that serves as a pointer to a resource on the World Wide Web, on your computer or on any networked machine. A `URL` object is more often used when accessing data over the Internet, while a simple string is more often used when accessing data on the current machine. Using an `URL` object also enables the programmer to access information from the Web, such as searching for information from a database or through a search engine.

Figure 21.1. Loading and displaying an image in an applet.

(This item is displayed on pages 980 - 981 in the print version)

```
1 // Fig. 21.1: LoadImageAndScale.java
2 // Load an image and display it in its original size and twice its
3 // original size. Load and display the same image as an ImageIcon.
4 import java.awt.Graphics;
5 import java.awt.Image;
6 import javax.swing.ImageIcon;
7 import javax.swing.JApplet;
8
9 public class LoadImageAndScale extends JApplet
10 {
11 private Image image1; // create Image object
12 private ImageIcon image2; // create ImageIcon object
13
14 // load image when applet is loaded
15 public void init()
16 {
17 image1 = getImage(getDocumentBase(), "redflowers.png");
18 image2 = new ImageIcon("yellowflowers.png");
19 } // end method init
20
21 // display image
22 public void paint(Graphics g)
23 {
24 super.paint(g);
25
26 g.drawImage(image1, 0, 0, this); // draw original image
```

```

27
28 // draw image to fit the width and the height less 120 pixels
29 g.drawImage(image1, 0, 120, getWidth(), getHeight() - 120, this);
30
31 // draw icon using its paintIcon method
32 image2.paintIcon(this, g, 180, 0);
33 } // end method paint
34 } // end class LoadImageAndScale

```

Lines 11 and 12 declare an `Image` reference and an `ImageIcon` reference, respectively. Class `Image` is an `abstract` class; the applet cannot create an object of class `Image` directly. Rather, we must call a method that causes the applet container to load and return the `Image` for use in the program. Class `Applet` (the direct superclass of `JApplet`) provides method `getImage` (line 17, in method `init`) that loads an `Image` into an applet. This version of `getImage` takes two arguments: the location of the image file and the file name of the image. In the first argument, `Applet` method `getDocumentBase` returns a `URL` representing the location of the image on the Internet (or on your computer if the applet was loaded from your computer). Method `getDocumentBase` returns the location of the HTML file as an object of class `URL`. The second argument specifies an image file name. The two arguments together specify the unique name and path of the file being loaded (in this case, the file `redflowers.png` stored in the same directory as the HTML file that invoked the applet). Java supports several image formats, including [Graphics Interchange Format \(GIF\)](#), [Joint Photographic Experts Group \(JPEG\)](#) and [Portable Network Graphics \(PNG\)](#). File names for these types end with `.gif`, `.jpg` (or `.jpeg`) and `.png`, respectively.

*Class `Image` is an **abstract** class as a result, programs cannot instantiate class `Image` to create objects. To achieve platform independence, the Java implementation on each platform provides its own subclass of `Image` to store image information.*

Line 17 begins loading the image from the local computer (or downloading it from the Internet). When the image is required by the program, it is loaded in a separate thread of execution. Remember that a thread is a parallel activity, and that threads will be discussed in detail in [Chapter 23](#), Multithreading. By using a separate thread to load an image, the program can continue execution while the image loads. [*Note:* If the requested file is not available, method `getImage` does not throw an exception. An `Image` object is returned, but when this `Image` is displayed using method `drawImage`, nothing will be displayed.]

Class `ImageIcon` is not an **abstract** class a program can create an `ImageIcon` object. At line 18, in method `init` creates an `ImageIcon` object that loads `yellowflowers.png`. Class `ImageIcon` provides several constructors that enable programs to initialize `ImageIcon` objects with images from the local computer or stored on the Internet.

The applet's `paint` method (lines 22-33) displays the images. Line 26 uses `Graphics` method `drawImage` to display an `Image`. Method `drawImage` accepts four arguments. The first is a reference to the `Image` object to display (`image1`). The second and third are the *x*- and *y*-coordinates at which to display the image on the applet the coordinates specify the location of the upper-left corner of the image. The last argument is a reference to an `ImageObserver` an interface implemented by class `Component`. Since class `JApplet` indirectly extends `Component`, all `JApplets` are `ImageObservers`. This argument is important when displaying large images that require a long time to download from the Internet. It is possible that a program will attempt to display the image before it has downloaded completely. The `ImageObserver` receives notifications as the `Image` is loaded and updates the image on the screen if the image was not complete when it was displayed. When executing this applet, watch carefully as pieces of the image display while the image loads. [*Note:* On faster computers, you might not notice this effect.]

Line 29 uses another version of `Graphics` method `drawImage` to output a scaled version of the image. The fourth and fifth arguments specify the *width* and *height* of the image for display purposes. Method `drawImage` scales the image to fit the specified width and height. In this example, the fourth argument indicates that the width of the scaled image should be the width of the applet, and the fifth argument indicates that the height should be 120 pixels less than the height of the applet. The width and height of the applet are determined by calling methods `getWidth` and `getHeight` (inherited from class `Component`).

Line 32 uses `ImageIcon` method `paintIcon` to display the image. The method requires four arguments a reference to the `Component` on which to display the image, a reference to the `Graphics` object that will render the image, the *x*-coordinate of the upper-left corner of the image and the *y*-coordinate of the upper-left corner of the image.

## 21.3. Animating a Series of Images

The next example demonstrates animating a series of images that are stored in an array of `ImageIcons`. The animation presented in [Fig. 21.2](#)[Fig. 21.3](#) is implemented using a subclass of `JPanel` called `LogoAnimatorJPanel` ([Fig. 21.2](#)) that can be attached to an application window or a `JApplet`. Class `LogoAnimator` ([Fig. 21.3](#)) declares a main method (lines 820 of [Fig. 21.3](#)) to execute the animation as an application. Method `main` declares an instance of class `JFrame` and attaches a `LogoAnimatorJPanel` object to the `JFrame` to display the animation.

Figure 21.2. Animating a series of images.

7 // execute animation in a JFrame
8 public static void main(String args[])
9 {
10 LogoAnimatorJPanel animation = new LogoAnimatorJPanel();
11
12 JFrame window = new JFrame("Animator test"); // set up window
13 window.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
14 window.add(animation); // add panel to frame
15
16 window.pack(); // make window just large enough for its GUI
17 window.setVisible(true); // display window
18
19 animation.startAnimation(); // begin animation
20 } // end main
21 } // end class LogoAnimator
```

[\[View full size image\]](#)

Class `LogoAnimatorJPanel` (Fig. 21.2) maintains an array of `ImageIcons` that are loaded in the constructor (lines 2436). Lines 2931 create each `ImageIcon` object and store the animation's 30 images in array `images`. The constructor argument uses string concatenation to assemble the file name from the pieces "images/", `IMAGE_NAME`, `count` and ".gif". Each image in the animation is in a file called `deitel# .gif`, where # is a value in the range 029 specified by the loop's control variable `count`. Lines 3435 determine the width and height of the animation from the size of the first image in array `images` we assume that all the images have the same width and height.

After the `LogoAnimatorJPanel` constructor loads the images, method `main` of Fig. 21.3 sets up the window in which the animation will appear (lines 1217), and line 19 calls the `LogoAnimatorJPanel`'s `startAnimation` method (declared at lines 5168 of Fig. 21.2). This method starts the program's animation for the first time or restarts the animation that the program stopped previously. [Note: This method is called when the program is first run, to begin the animation. Although we provide the functionality for this method to restart the animation if it has been stopped, the example does not call the method for this purpose. We have added the functionality, however, should the reader choose to add GUI components that enable the user to start and stop the animation.] For example, to make an animation "browser friendly" in an applet, the animation should stop when the user switches Web pages. If the user returns to the Web page with the animation, method `startAnimation` can be called to restart the animation. The animation is driven by an instance of class `Timer` (from package `javax.swing`). A `Timer` generates `ActionEvents` at a fixed interval in milliseconds (normally specified as an argument to the `Timer`'s constructor) and notifies all its `ActionListeners` each time an `ActionEvent` occurs. Line 53 determines whether the `Timer` reference `animationTimer` is `null`. If it is,

method `startAnimation` is being called for the first time, and a `Timer` needs to be created so that the animation can begin. Line 55 sets `currentImage` to 0, which indicates that the animation should begin with the image in the first element of array `images`. Lines 58-59 assign a new `Timer` object to `animationTimer`. The `Timer` constructor receives two arguments: the delay in milliseconds (`ANIMATION_DELAY` is 50, as specified in line 17) and the `ActionListener` that will respond to the `Timer`'s `ActionEvents`. For the second argument, an object of class `TimerHandler` is created. This class, which implements `ActionListener`, is declared in lines 89-96. Line 61 starts the `Timer` object. Once started, `animationTimer` will generate an `ActionEvent` every 50 milliseconds. Each time an `ActionEvent` is generated, the `Timer`'s event handler `actionPerformed` (lines 92-95) is called. Line 94 calls `LogoAnimatorJPanel`'s `repaint` method to schedule a call to `LogoAnimatorJPanel`'s `paintComponent` method (lines 39-48). Remember that any subclass of `JComponent` that draws should do so in its `paintComponent` method. Recall from [Chapter 11](#) that the first statement in any `paintComponent` method should be a call to the superclass's `paintComponent` method, to ensure that Swing components are displayed correctly.

---

[Page 983]

---

[Page 984]

---

[Page 985]

If the animation was started earlier, then our `Timer` has been created and the condition in line 53 will evaluate to `false`. The program will continue with lines 65-66, which restart the animation that the program stopped previously. The `if` condition at line 65 uses `Timer` method `isRunning` to determine whether the `Timer` is running (i.e., generating events). If it is not running, line 66 calls `Timer` method `restart` to indicate that the `Timer` should start generating events again. Once this occurs, method `actionPerformed` (the `Timer`'s event handler) is again called at regular intervals. Each time, a call is made to method `repaint` (line 94), causing method `paintComponent` to be called and the next image to be displayed.

---

[Page 986]

---

Line 43 paints the `ImageIcon` stored at element `currentImage` in the array. Lines 46-47 determine whether the `animationTimer` is running and, if so, prepare for the next image to be displayed by incrementing `currentImage` by 1. The remainder calculation ensures that the value of `currentImage` is set to 0 (to repeat the animation sequence) when it is incremented past 29 (the last element index in the array). The `if` statement ensures that the same image will be displayed if `paintComponent` is called while the `Timer` is stopped. This could be useful if a GUI is provided that enables the user to start and stop the animation. For example, if the animation is stopped and the user covers it with another window, then uncovers it, method `paintComponent` will be called. In this case, we do not want the animation to show the next image (because the animation has been stopped). We simply want the window to display the same image until the animation is restarted.

Method `stopAnimation` (lines 71-74) stops the animation by calling `Timer` method `stop` to indicate that the `Timer` should stop generating events. This prevents `actionPerformed` from calling `repaint` to initiate the painting of the next image in the array. [Note: Just as with restarting the animation, this example defines but does not use method `stopAnimation`. We have provided this method for demonstration purposes, or if the user wishes to modify this example so that it enables the user to stop and restart the animation.]

## Software Engineering Observation 21.1

*When creating an animation for use in an applet, provide a mechanism for disabling the animation when the user browses a new Web page different from the one on which the animation applet resides.*

Remember that by extending class `JPanel`, we are creating a new GUI component. Thus, we must ensure that our new component works like other components for layout purposes. Layout managers often use a GUI component's `getPreferredSize` method (inherited from class `java.awt.Component`) to determine the preferred width and height of the component when laying it out as part of a GUI. If a new component has a preferred width and height, it should override method `getPreferredSize` (lines 8386) to return that width and height as an object of class `Dimension` (package `java.awt`). The `Dimension` class represents the width and height of a GUI component. In this example, the images are 160 pixels wide and 80 pixels tall, so method `getPreferredSize` returns a `Dimension` object containing the numbers 160 and 80 (determined at lines 3435).

## Look-and-Feel Observation 21.1

*The default size of a `JPanel` object is 10 pixels wide and 10 pixels tall.*

## Look-and-Feel Observation 21.2

*When subclassing `JPanel` (or any other `JComponent`), override method `getPreferredSize` if the new component is to have a specific preferred width and height.*

---

[Page 987]

Lines 7780 override method `getMinimumSize`. This method determines the minimum width and height of the component. As with method `getPreferredSize`, new components should override method `getMinimumSize` (also inherited from class `Component`). Method `getMinimumSize` simply calls `getPreferredSize` (a common programming practice) to indicate that the minimum size and preferred size are the same. Some layout managers ignore the dimensions specified by these methods. For example, a `BorderLayout`'s `NORTH` and `SOUTH` regions use only the component's preferred height.

## Look-and-Feel Observation 21.3

*If a new GUI component has a minimum width and height (i.e., smaller dimensions would render the component ineffective on the display), override method `getMinimumSize` to return the minimum width and height as an instance of class `Dimension`.*

## Look-and-Feel Observation 21.4

*For many GUI components, method `getMinimumSize` is implemented to return the result of a call to the component's `getPreferredSize` method.*

## 21.4. Image Maps

**Image maps** are commonly used to create interactive Web pages. An image map is an image with **hot areas** that the user can click to accomplish a task, such as loading a different Web page into a browser. When the user positions the mouse pointer over a hot area, normally a descriptive message appears in the status area of the browser or in a tool tip.

**Figure 21.4** loads an image containing several of the programming tip icons used in this book. The program allows the user to position the mouse pointer over an icon to display a descriptive message associated with it. Event handler `mouseMoved` (lines 3943) takes the mouse coordinates and passes them to method `translateLocation` (lines 5869). Method `translateLocation` tests the coordinates to determine the icon over which the mouse was positioned when the `mouseMoved` event occurred; the method then returns a message indicating what the icon represents. This message is displayed in the applet container's status bar using method `showStatus` of class `Applet`.

62 return "";
63
64 // determine icon number (0 - 6)
65 double iconWidth = (double) mapImage.getIconWidth() / 7.0;
66 int iconNumber = (int)((double) x / iconWidth);
67
68 return captions[iconNumber]; // return appropriate icon caption
69 } // end method translateLocation
70 } // end class ImageMap

```

[\[View full size image\]](#)

Clicking in the applet of [Fig. 21.4](#) will not cause any action. In [Chapter 24](#), Networking, we discuss the techniques required to load another Web page into a browser via [URLs](#) and the [AppletContext](#) interface. Using those techniques, this applet could associate each icon with a [URL](#) that the browser would display when the user clicks the icon.

## 21.5. Loading and Playing Audio Clips

Java programs can manipulate and play [audio clips](#). Users can capture their own audio clips, and many clips are available in software products and over the Internet. Your system needs to be equipped with audio hardware (speakers and a sound card) to be able to play the audio clips.

Java provides several mechanisms for playing sounds in an applet. The two simplest are the `Applet`'s `play` method and the `play` method of the `AudioClip` interface. Additional audio capabilities are available in the Java Media Framework and Java Sound APIs. If you would like to play a sound once in a program, the `Applet` method `play` loads the sound and plays it once the sound is marked for garbage collection after it plays. The `Applet` method `play` has two versions:

```
[Page 988] public void play(URL location, String soundFileName);
 public void play(URL soundURL);
```

The first version loads the audio clip stored in file `soundFileName` from `location` and plays the sound. The first argument is normally a call to the applet's `getDocumentBase` or `getCodeBase` method. Method `getDocumentBase` returns the location of the HTML file that loaded the applet. (If the applet is in a package, the method returns the location of the package or the JAR file containing the package.) Method `getCodeBase` indicates the location of the applet's `.class` file. The second version of method `play` takes a `URL` that contains the location and the file name of the audio clip. The statement

---

[Page 990]

```
play(getDocumentBase(), "hi.au");
```

loads the audio clip in file `hi.au` and plays the clip once.

---

[Page 991]

The [sound engine](#) that plays the audio clips supports several audio file formats, including [Sun Audio file format](#) (`.au` extension), [Windows Wave file format](#) (`.wav` extension), [Macintosh AIFF file format](#) (`.aif` or `.aiff` extensions) and [Musical Instrument Digital Interface \(MIDI\) file format](#) (`.mid` or `.rmi` extensions). The Java Media Framework (JMF) and Java Sound APIs support additional formats.

The program of [Fig. 21.5](#) demonstrates loading and playing an `AudioClip` (package `java.applet`). This technique is more flexible than `Applet` method `play`. An applet can use an `AudioClip` to store audio for repeated use throughout a program's execution.

### Figure 21.5. Loading and playing an `AudioClip`.

(This item is displayed on pages 991 - 992 in the print version)

```
1 // Fig. 21.5: LoadAudioAndPlay.java
2 // Load an audio clip and play it.
```

```

3 import java.applet.AudioClip;
4 import java.awt.event.ItemListener;
5 import java.awt.event.ItemEvent;
6 import java.awt.event.ActionListener;
7 import java.awt.event.ActionEvent;
8 import java.awt.FlowLayout;
9 import javax.swing.JApplet;
10 import javax.swing.JButton;
11 import javax.swing.JComboBox;
12
13 public class LoadAudioAndPlay extends JApplet
14 {
15 private AudioClip sound1, sound2, currentSound;
16 private JButton playJButton, loopJButton, stopJButton;
17 private JComboBox soundJComboBox;
18
19 // load the image when the applet begins executing
20 public void init()
21 {
22 setLayout(new FlowLayout());
23
24 String choices[] = { "Welcome", "Hi" };
25 soundJComboBox = new JComboBox(choices); // create JComboBox
26
27 soundJComboBox.addItemListener(
28
29 new ItemListener() // anonymous inner class
30 {
31 // stop sound and change to sound to user's selection
32 public void itemStateChanged(ItemEvent e)
33 {
34 currentSound.stop();
35 currentSound = soundJComboBox.getSelectedIndex() == 0 ?
36 sound1 : sound2;
37 } // end method itemStateChanged
38 } // end anonymous inner class
39); // end addItemListener method call
40
41 add(soundJComboBox); // add JComboBox to applet
42
43 // set up button event handler and buttons
44 ButtonHandler handler = new ButtonHandler();
45
46 // create Play JButton
47 playJButton = new JButton("Play");
48 playJButton.addActionListener(handler);
49 add(playJButton);
50
51 // create Loop JButton
52 loopJButton = new JButton("Loop");
53 loopJButton.addActionListener(handler);
54 add(loopJButton);
55
56 // create Stop JButton
57 stopJButton = new JButton("Stop");
58 stopJButton.addActionListener(handler);
59 add(stopJButton);
60
61 // load sounds and set currentSound
62 sound1 = getAudioClip(getDocumentBase(), "welcome.wav");
63 sound2 = getAudioClip(getDocumentBase(), "hi.au");

```

```

64 currentSound = sound1;
65 } // end method init
66
67 // stop the sound when the user switches Web pages
68 public void stop()
69 {
70 currentSound.stop(); // stop AudioClip
71 } // end method stop
72
73 // private inner class to handle button events
74 private class ButtonHandler implements ActionListener
75 {
76 // process play, loop and stop button events
77 public void actionPerformed(ActionEvent actionEvent)
78 {
79 if (actionEvent.getSource() == playJButton)
80 currentSound.play(); // play AudioClip once
81 else if (actionEvent.getSource() == loopJButton)
82 currentSound.loop(); // play AudioClip continuously
83 else if (actionEvent.getSource() == stopJButton)
84 currentSound.stop(); // stop AudioClip
85 } // end method actionPerformed
86 } // end class ButtonHandler
87 } // end class LoadAudioAndPlay

```

[Page 993]

Applet method `getAudioClip` has two forms that take the same arguments as method `play` described previously. Method `getAudioClip` returns a reference to an `AudioClip`. An `AudioClip` has three methods `play`, `loop` and `stop`. As mentioned earlier, method `play` plays the audio clip once. Method `loop` continuously loops through the audio clip in the background. Method `stop` terminates an audio clip that is currently playing. In the program, each of these methods is associated with a button on the applet.

Lines 62-63 in the applet's `init` method use `getAudioClip` to load two audio files: a Windows Wave file (`welcome.wav`) and a Sun Audio file (`hi.au`). The user can select which audio clip to play from the `JComboBox` `soundJComboBox`. Note that the applet's `stop` method is overridden at lines 68-71. When the user switches Web pages, the applet container calls the applet's `stop` method. This enables the applet to stop playing the audio clip. Otherwise, it continues to play in the background even if the applet is not displayed in the browser. This is not necessarily a problem, but it can be annoying to the user if the audio clip is looping. The `stop` method is provided here as a convenience to the user.

## Look-and-Feel Observation 21.5

*When playing audio clips in an applet or application, provide a mechanism for the user to disable the audio.*

## 21.6. Playing Video and Other Media with Java Media Framework

A simple video can concisely and effectively convey a great deal of information. Recognizing the value of bringing extensible multimedia capabilities to Java, Sun Microsystems, Intel and Silicon Graphics worked together to produce the multimedia API Java Media Framework (JMF), discussed briefly in [Section 21.1](#). Using the JMF API, programmers can create Java applications that play, edit, stream and capture many popular media types. While the features of JMF are quite extensive, this section briefly introduces some popular media formats and demonstrates playing video using the JMF API.

IBM and Sun developed the latest JMF specification version 2.0. Sun also provides a reference implementation of the JMF specification JMF 2.1.1 that supports media file types such as [Microsoft Audio/Video Interleave \(.avi\)](#), [Macromedia Flash 2 movies \(.swf\)](#), [Future Splash \(.spl\)](#), [MPEG Layer 3 Audio \(.mp3\)](#), Musical Instrument Digital Interface (MIDI; [.mid](#) or [.rmi](#) extensions), [MPEG-1 videos \(.mpeg, .mpg\)](#), [QuickTime \(.mov\)](#), Sun Audio file format ([.au](#) extension), and Macintosh AIFF file format ([.aif](#) or [.aiff](#) extension). You have already seen some of these file types.

Currently, JMF is available as an extension separate from the Java 2 Software Development Kit. The most recent JMF implementation (2.1.1e) can be downloaded from:

<http://java.sun.com/products/java-media/jmf/2.1.1/download.html>

You need to accept the license agreement prior to downloading.

The JMF Web site provides versions of the JMF that take advantage of the performance features of certain platforms. For example, the JMF Windows Performance Pack provides extensive media and device support for Java programs running on Microsoft Windows platforms (Windows 95/98/NT 4.0/2000/XP). JMF's official Web site ([java.sun.com/products/java-media/jmf](http://java.sun.com/products/java-media/jmf)) provides continually updated support, information and resources for JMF programmers.

---

[Page 994]

Once the file finishes downloading, open it and follow the on-screen instructions to install the program. Leave all options at their defaults. You may need to restart your computer to finish the installation.

### Creating a Simple Media Player

The JMF offers several mechanisms for playing media. The simplest mechanism is using objects that implement interface `Player` declared in package `javax.media`. Package `javax.media` and its subpackages contain the classes that compose the Java Media Framework. To play a media clip you must first create a `URL` object that refers to it. Then pass the `URL` as an argument to `static` method `createRealizedPlayer` of class `Manager` to obtain a `Player` for the media clip. Class `Manager` declares utility methods for accessing system resources to play and to manipulate media. [Figure 21.6](#) declares a `JPanel` that demonstrates some of these methods.

Figure 21.6. `JPanel` that plays a media file from a `URL`.

(This item is displayed on page 995 in the print version)

```

1 // Fig. 21.6: MediaPlayer.java
2 // A JPanel the plays media from a URL
3 import java.awt.BorderLayout;
4 import java.awt.Component;
5 import java.io.IOException;
6 import java.net.URL;
7 import javax.media.CannotRealizeException;
8 import javax.media.Manager;
9 import javax.media.NoPlayerException;
10 import javax.media.Player;
11 import javax.swing.JPanel;
12
13 public class MediaPlayer extends JPanel
14 {
15 public MediaPlayer(URL mediaURL)
16 {
17 setLayout(new BorderLayout()); // use a BorderLayout
18
19 // Use lightweight components for Swing compatibility
20 Manager.setHint(Manager.LIGHTWEIGHT_RENDERER, true);
21
22 try
23 {
24 // create a player to play the media specified in the URL
25 Player mediaPlayer = Manager.createRealizedPlayer(mediaURL);
26
27 // get the components for the video and the playback controls
28 Component video = mediaPlayer.getVisualComponent();
29 Component controls = mediaPlayer.getControlPanelComponent();
30
31 if (video != null)
32 add(video, BorderLayout.CENTER); // add video component
33
34 if (controls != null)
35 add(controls, BorderLayout.SOUTH); // add controls
36
37 mediaPlayer.start(); // start playing the media clip
38 } // end try
39 catch (NoPlayerException noPlayerException)
40 {
41 System.err.println("No media player found");
42 } // end catch
43 catch (CannotRealizeException cannotRealizeException)
44 {
45 System.err.println("Could not realize media player");
46 } // end catch
47 catch (IOException iOException)
48 {
49 System.err.println("Error reading from the source");
50 } // end catch
51 } // end MediaPlayer constructor
52 } // end class MediaPlayer

```

The constructor (lines 15-51) sets up the `JPanel` to play the media file specified as a `URL` parameter to the constructor. `MediaPlayer` uses a `BorderLayout` (line 17). Line 20 invokes `static` method `setHint` to set the flag `Manager.LIGHTWEIGHT_RENDERER` to `True`. This instructs the `Manager` to use a lightweight renderer that is compatible with lightweight Swing components, as opposed to the default heavyweight renderer. Inside the

`try` block (lines 2238), line 25 invokes `static` method `createRealizedPlayer` of class `Manager` to create and realize a `Player` that plays the media file. When a `Player` realizes, it identifies the system resources it needs to play the media. Depending on the file, realizing can be a resource-consuming and time-consuming process. Method `createRealizedPlayer` throws three checked exceptions, `NoPlayerException`, `CannotRealizeException` and `IOException`. A `NoPlayerException` indicates that the system could not find a player that can play the file format. A `CannotRealizeException` indicates that the system could not properly identify the resources a media file needs. An `IOException` indicates that there was an error while reading the file. These exceptions are handled in the `catch` block in lines 3950.

Line 28 invokes method `getVisualComponent` of `Player` to get a `Component` that displays the visual (generally video) aspect of the media file. Line 29 invokes method `getControlPanelComponent` of `Player` to get a `Component` that provides playback and media controls. These components are assigned to local variables `video` and `control`, respectively. The `if` statements in lines 3132 and lines 3435 add the `video` and the controls if they exist. The `video` `Component` is added to the `CENTER` region (line 32), so it fills any available space on the `JPanel`. The `controls` `Component`, which is added to the `SOUTH` region, typically provides the following controls:

1. A positioning slider to jump to certain points in the media clip.
2. A pause button.
3. A volume button that provides volume control by right clicking and a mute function by left clicking.
4. A media properties button that provides detailed media information by left clicking and frame rate control by right clicking.

Line 37 calls `Player` method `start` to begin playing the media file. Lines 3950 handle the various exceptions that `createRealizedPlayer` throws.

---

[Page 996]

The application in [Fig. 21.7](#) displays a `JFileChooser` dialog for the user to choose a media file. It then creates a `MediaPanel` that plays the selected file and creates a `JFrame` to display the `MediaPanel`.

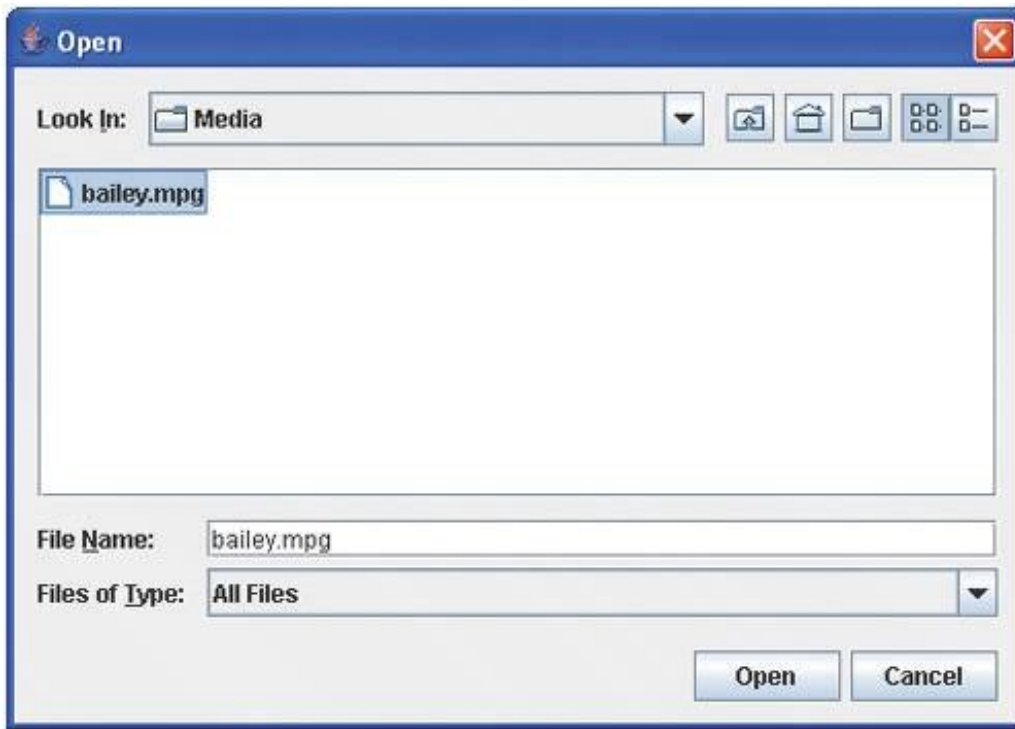

Figure 21.7. Test application that creates a `MediaPanel` from a user-selected file.

(This item is displayed on pages 996 - 997 in the print version)

```
1 // Fig. 21.7: MediaTest.java
2 // A simple media player
3 import java.io.File;
4 import java.net.MalformedURLException;
5 import java.net.URL;
6 import javax.swing.JFileChooser;
7 import javax.swing.JFrame;
8
9 public class MediaTest
10 {
11 // launch the application
12 public static void main(String args[])
13 {
14 // create a file chooser
15 JFileChooser fileChooser = new JFileChooser();
16
17 // show open file dialog
```

```
18 int result = fileChooser.showOpenDialog(null);
19
20 if (result == JFileChooser.APPROVE_OPTION) // user chose a file
21 {
22 URL mediaURL = null;
23
24 try
25 {
26 // get the file as URL
27 mediaURL = fileChooser.getSelectedFile().toURL();
28 } // end try
29 catch (MalformedURLException malformedURLException)
30 {
31 System.err.println("Could not create URL for the file");
32 } // end catch
33
34 if (mediaURL != null) // only display if there is a valid URL
35 {
36 JFrame mediaTest = new JFrame("Media Tester");
37 mediaTest.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
38
39 MediaPanel mediaPanel = new MediaPanel(mediaURL);
40 mediaTest.add(mediaPanel);
41
42 mediaTest.setSize(300, 300);
43 mediaTest.setVisible(true);
44 } // end inner if
45 } // end outer if
46 } // end main
47 } // end class MediaTest
```

[\[View full size image\]](#)

[Page 997]

Method `main` (lines 1246) assigns a new `JFileChooser` to local variable `fileChooser` (line 15), shows an open file dialog (line 18) and assigns the return value to `result`. Line 20 checks `result` to determine whether the user chose a file. To create a `Player` to play the selected media file, you must convert the `File` object returned by `JFileChooser` to a `URL` object. Method `toURL` of class `File` returns a `URL` that points to the File on the system, possibly throwing a `MalformedURLException` if it cannot create a `URL` object for the `File`. The `try` statement (lines 2432) creates a `URL` for the selected file and assigns it to `mediaURL`. The `if` statement in lines 3444 checks that `mediaURL` is not `null` and creates the GUI components to play the media.

## 21.7. Wrap-Up

In this chapter, you learned how to make applications more exciting by including sound, images, graphics and video. We introduced Java's multimedia capabilities, including the Java Media Framework API, Java Sound API and Java 3D API. You used classes `Image` and `ImageIcon` to display and manipulate images stored in files, and you learned about the different image formats supported by Java. You created animation by displaying a series of images in a specific order. You used image maps to make an application more interactive. You then learned how to load audio clips, and how to play them either once or in a continuous loop. The chapter concluded with a demonstration of loading and playing video. In the next chapter, you will continue your study of GUI concepts, building on the techniques you learned in [Chapter 11](#).

## 21.8. Internet and Web Resources

[www.nasa.gov/multimedia/highlights/index.html](http://www.nasa.gov/multimedia/highlights/index.html)

The *NASA Multimedia Gallery* contains a wide variety of images, audio clips and video clips that you can download and use to test your Java multimedia programs.

[sunsite.tus.ac.jp/multimed](http://sunsite.tus.ac.jp/multimed)

The *Sunsite Japan Multimedia Collection* also provides a wide variety of images, audio clips and video clips that you can download for educational purposes.

[www.anbg.gov.au/anbg/index.html](http://www.anbg.gov.au/anbg/index.html)

The *Australian National Botanic Gardens* Web site provides links to the sounds of many animals. Try, for example, the *Common Birds* link under the "Animals in the Gardens" section.

[www.thefreesite.com](http://www.thefreesite.com)

*TheFreeSite.com* has links to free sounds and clip art.

[www.soundcentral.com](http://www.soundcentral.com)

*SoundCentral* provides audio clips in WAV, AU, AIFF and MIDI formats.

[www.animationfactory.com](http://www.animationfactory.com)

The *Animation Factory* provides thousands of free GIF animations for personal use.

[www.clipart.com](http://www.clipart.com)

*ClipArt.com* is a subscription-based service for images and sounds.

[www.pngart.com](http://www.pngart.com)

PNGART.com provides over 50,000 free images in PNG format.

[java.sun.com/developer/techDocs/hi/repository](http://java.sun.com/developer/techDocs/hi/repository)

The *Java look and feel Graphics Repository* provides images designed for use in a Swing GUI, including toolbar button images.

[www.freebyte.com/graphicprograms](http://www.freebyte.com/graphicprograms)

This guide contains links to several free graphics software programs. The software can be used to modify images and draw graphics.

[graphicssoft.about.com/od/pixelbasedfreewin](http://graphicssoft.about.com/od/pixelbasedfreewin)

This site provides links for free graphics programs designed for use on Windows machines.

## Java Multimedia API References

The *Java Advanced Imaging API* home page. This API provides image-processing capabilities, such as contrast enhancement, cropping, scaling and geometric warping.

[java.sun.com/products/java-media/speech](http://java.sun.com/products/java-media/speech)

The *Java Speech API* enables programs to perform speech synthesis and speech recognition.

[freetts.sourceforge.net/docs/index.php](http://freetts.sourceforge.net/docs/index.php)

*FreeTTS* is an implementation of the Java Speech API.

[java.sun.com/products/java-media/2D](http://java.sun.com/products/java-media/2D)

This is the *Java 2D API* home page. This API (introduced in [Chapter 12](#)) provides complex two-dimensional graphics capabilities.

[java.sun.com/j2se/1.4.2/docs/guide/imageio](http://java.sun.com/j2se/1.4.2/docs/guide/imageio)

This site contains a guide to the *Java Image I/O API*, which enables programs to load and save images using formats that are not currently supported by the Java APIs.

## Summary

- `Applet` method `getImage` loads an `Image`.
- `Applet` method `getDocumentBase` returns the location of the applet's HTML file on the Internet as an object of class `URL`.
- Java supports several image formats, including Graphics Interchange Format (GIF), Joint Photographic Experts Group (JPEG) and Portable Network Graphics (PNG). The file names for these types end with `.gif`, `.jpg` (or `.jpeg`) and `.png`, respectively.
- Class `ImageIcon` provides constructors that allow an `ImageIcon` object to be initialized with an image from the local computer or stored on a Web server on the Internet.
- `Graphics` method `drawImage` accepts four arguments: a reference to the `Image` object in which the image is stored, the  $x$ - and  $y$ -coordinates where the image should be displayed and a reference to an `ImageObserver` object.
- Another version of `Graphics` method `drawImage` outputs a scaled image. The fourth and fifth arguments specify the width and height of the image for display purposes.
- Interface `ImageObserver` is implemented by class `Component`. `ImageObservers` receive notifications as an `Image` is loaded and update the image on the screen if it was not complete when it was displayed.
- `ImageIcon` method `paintIcon` displays the `ImageIcon`'s image. The method requires four arguments: a reference to the `Component` on which the image will be displayed, a reference to the `Graphics` object used to render the image, the  $x$ -coordinate of the upper-left corner of the image and the  $y$ -coordinate of the upper-left corner of the image.
- A `URL` object represents a Uniform Resource Locator, which is as a pointer to a resource on the World Wide Web, on your computer or on any networked machine.
- `Timer` objects generate `ActionEvents` at fixed intervals in milliseconds. The `Timer` constructor receives two arguments: the delay in milliseconds and the `ActionListener`. `Timer` method `start` indicates that the `Timer` should `start` generating events. `Timer` method `stop` indicates that the `Timer` should `stop` generating events. `Timer` method `restart` indicates that the `Timer` should start generating events again.
- An image map is an image that has hot areas that the user can click to accomplish a task, such as loading a different Web page into a browser.
- `Applet` method `play` has two forms:

```
[Page 1000] public void play(URL location, String soundFileName);
 public void play(URL soundURL);
```

One version loads the audio clip stored in file `soundFileName` from `location` and plays the sound. The other version takes a `URL` that contains the location and the file name of the audio clip.

- `Applet` method `getDocumentBase` indicates the location of the HTML file that loaded the applet. Method `getCodeBase` indicates where the `.class` file for an applet is located.
- The sound engine that plays audio clips supports several audio file formats, including Sun Audio file format (`.au` extension), Windows Wave file format (`.wav` extension), Macintosh AIFF file format (`.aif` or `.aiff` extension) and Musical Instrument Digital Interface (MIDI) file format (`.mid` or `.rmi`).

extensions). The Java Media Framework (JMF) supports additional formats.

- Applet method `getAudioClip` has two forms that take the same arguments as the `play` method. Method `getAudioClip` returns a reference to an `AudioClip`. `AudioClips` have three methods `play`, `loop` and `stop`. Method `play` plays the audio clip once. Method `loop` continuously loops the audio clip. Method `stop` terminates an audio clip that is currently playing.
- Sun Microsystems, Intel and Silicon Graphics worked together to produce the Java Media Framework (JMF)
- Package `javax.media` and its subpackages contain the classes that compose the Java Media Framework.
- Class `Manager` declares utility methods for accessing system resources to play and to manipulate media.
- Method `toURL` of class `File` returns a `URL` that points to the `File` on the system.

## Self-Review Exercises

21.1 Fill in the blanks in each of the following statements:

- a. `Applet` method \_\_\_\_\_ loads an image into an applet.
- b. `Graphics` method \_\_\_\_\_ displays an image on an applet.
- c. Java provides two mechanisms for playing sounds in an applet: the `Applet`'s `play` method and the `play` method of the \_\_\_\_\_ interface.
- d. A(n) \_\_\_\_\_ is an image that has hot areas that the user can click to accomplish a task such as loading a Web page.
- e. Method \_\_\_\_\_ of class `ImageIcon` displays the `ImageIcon`'s image.
- f. Java supports several image formats, including \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.

21.2 Determine whether each of the following statements is *true* or *false*. If *false*, explain why.

- a. A sound is marked for garbage collection after it plays.
- b. Class `ImageIcon` provides constructors that allow an `ImageIcon` object to be initialized only with an image from the local computer.
- c. Method `play` of class `AudioClip` continuously loops an audio clip.
- d. The Java Image I/O API is used for adding 3D graphics to a Java application.
- e. `Applet` method `getDocumentBase` returns, as an object of class `URL`, the location on the Internet of the HTML file that invoked the applet.

## Answers to Self-Review Exercises

[21.1](#) a) `getImage`. b) `drawImage`. c) `AudioClip`. d) image map. e) `paintIcon`. f) Graphics Interchange Format (GIF), Joint Photographic Experts Group (JPEG), Portable Network Graphics (PNG).

[21.2](#) a) True. b) False. `ImageIcon` can load images from the Internet as well. c) False. Method `play` of class `AudioClip` plays an audio clip once. Method `loop` of class `AudioClip` continuously loops an audio clip. d) False. The Java 3D API is used for creating and modifying 3D graphics. The Java Image I/O API is used for reading from and outputting images to files. e) True.

## Exercises

- 21.3 Describe how to make an animation "browser friendly."
- 21.4 Describe the Java methods for playing and manipulating audio clips.

- 21.5 Explain how image maps are used. List several examples of their use.
- 21.6 *(Randomly Erasing an Image)* Suppose an image is displayed in a rectangular screen area. One way to erase the image is simply to set every pixel to the same color immediately, but this is a dull visual effect. Write a Java program that displays an image and then erases it by using random-number generation to select individual pixels to erase. After most of the image is erased, erase all the remaining pixels at once. You can draw individual pixels as a line that starts and ends at the same coordinates. You might try several variants of this problem. For example, you might display lines randomly or display shapes randomly to erase regions of the screen.
- 21.7 *(Text Flasher)* Create a Java program that repeatedly flashes text on the screen. Do this by alternating the text with a plain background-color image. Allow the user to control the "blink speed" and the background color or pattern. You will need to use methods `getDelay` and `setDelay` of class `Timer`. These methods are used to retrieve and set the interval in milliseconds between `ActionEvents`, respectively
- 21.8 *(Image Flasher)* Create a Java program that repeatedly flashes an image on the screen. Do this by alternating the image with a plain background-color image.
- 21.9 *(Digital Clock)* Implement a program that displays a digital clock on the screen.
- 21.10 *(Calling Attention to an Image)* If you want to emphasize an image, you might place a row of simulated light bulbs around it. You can let the light bulbs flash in unison or fire on and off in sequence one after the other.
- 21.11 *(Image Zooming)* Create a program that enables you to zoom in on or out from an image.

## Special Section: Challenging Multimedia Projects

The preceding exercises are keyed to the text and designed to test the reader's understanding of fundamental multimedia concepts. This section includes a collection of advanced multimedia projects. The reader should find these problems challenging, yet entertaining. The problems vary considerably in difficulty. Some require an hour or two of program writing and implementation. Others are useful for lab assignments that might require two or three weeks of study and implementation. Some are challenging term projects. [*Note to Instructors:* Solutions are not provided for these exercises.]

- 21.12 (*Animation*) Create a general-purpose Java animation program. It should allow the user to specify the sequence of frames to be displayed, the speed at which the images are displayed, audios to be played while the animation is running and so on.
- 21.13 (*Limericks*) Modify the limerick-writing program you wrote in [Exercise 10.10](#) to sing the limericks your program creates.
- 21.14 (*Random Interimage Transition*) This provides a nice visual effect. If you are displaying one image in a given area on the screen and you would like to transition to another image in the same area, store the new screen image in an off-screen buffer and randomly copy pixels from it to the display area, overlaying the pixels already at those locations. When the vast majority of the pixels have been copied, copy the entire new image to the display area to be sure you are displaying the complete new image. To implement this program, you may need to use the `PixelGrabber` and `MemoryImageSource` classes (see the Java API documentation for descriptions of these classes). You might try several variants of this problem. For example, try selecting all the pixels in a randomly selected straight line or shape in the new image, and overlay them above the corresponding positions of the old image.
- 21.15 (*Background Audio*) Add background audio to one of your favorite applications by using the `loop` method of class `AudioClip` to play the sound in the background while you interact with your application in the normal way.

---

[Page 1003]

- 21.16 (*Scrolling Marquee Sign*) Create a Java program that scrolls dotted characters from right to left (or from left to right if that is appropriate for your language) across a marquee-like display sign. As an option, display the text in a continuous loop, so that after the text disappears at one end, it reappears at the other.
- 21.17 (*Scrolling Image Marquee*) Create a Java program that scrolls an image across a marquee screen.
- 21.18 (*Analog Clock*) Create a Java program that displays an analog clock with hour, minute and second hands that move appropriately as the time changes.
- 21.19 (*Dynamic Audio and Graphical Kaleidoscope*) Write a kaleidoscope program that displays reflected graphics to simulate the popular children's toy. Incorporate audio effects that "mirror" your program's dynamically changing graphics.
- 21.20 (*Automatic Jigsaw Puzzle Generator*) Create a Java jigsaw puzzle generator and manipulator. The user specifies an image. Your program loads and displays the image, then breaks it into randomly selected shapes and shuffles them. The user then uses the mouse to move the pieces around to solve the puzzle. Add appropriate audio sounds as the pieces are moved

around and snapped back into place. You might keep tabs on each piece and where it really belongsthen use audio effects to help the user get the pieces into the correct positions.

- 21.21 *(Maze Generator and Walker)* Develop a multimedia-based maze generator and traverser program based on the maze programs you wrote in [Exercise 15.20](#)[Exercise 15.22](#). Let the user customize the maze by specifying the number of rows and columns and by indicating the level of difficulty. Have an animated mouse walk the maze. Use audio to dramatize the movement of your mouse character.
- 21.22 *(One-Armed Bandit)* Develop a multimedia simulation of a "one-armed bandit." Have three spinning wheels. Place images of various fruits and symbols on each wheel. Use true random-number generation to simulate the spinning of each wheel and the stopping of each wheel on a symbol.
- 21.23 *(Horse Race)* Create a Java simulation of a horse race. Have multiple contenders. Use audios for a race announcer. Play the appropriate audios to indicate the correct status of each contender throughout the race. Use audios to announce the final results. You might try to simulate the kinds of horse-racing games that are often played at carnivals. The players take turns at the mouse and have to perform some skill-oriented manipulation with it to advance their horses.
- 21.24 *(Shuffleboard)* Develop a multimedia-based simulation of the game of shuffleboard. Use appropriate audio and visual effects.
- 21.25 *(Game of Pool)* Create a multimedia-based simulation of the game of pool. Each player takes turns using the mouse to position a pool cue and hit it against the ball at the appropriate angle to try to make other balls fall into the pockets. Your program should keep score.
- 21.26 *(Artist)* Design a Java art program that will give an artist a great variety of capabilities to draw, use images and use animations to create a dynamic multimedia art display.
- 21.27 *(Fireworks Designer)* Create a Java program that someone might use to create a fireworks display. Create a variety of fireworks demonstrations. Then orchestrate the firing of the fireworks for maximum effect.
- 21.28 *(Floor Planner)* Develop a Java program that will help someone arrange furniture in a home. Add features that enable the person to achieve the best possible arrangement.
- 21.29 *(Crossword)* Crossword puzzles are among the most popular pastimes. Develop a multimedia-based crossword-puzzle program. Your program should enable the player to place and erase words easily. Tie your program to a large computerized dictionary. Your program also should be able to suggest words on which letters have already been filled in. Provide other features that will make the crossword-puzzle enthusiast's job easier.

- 21.30 *(15 Puzzle)* Write a multimedia-based Java program that enables the user to play the game of 15. The game is played on a 4-by-4 board for a total of 16 slots. One slot is empty, the others are occupied by 15 tiles numbered 1 through 15. Any tile next to the currently empty slot can be moved into that slot by clicking on the tile. Your program should create the board with the tiles out of order. The goal is to arrange the tiles into sequential order, row by row.
- 21.31 *(Reaction Time/Reaction Precision Tester)* Create a Java program that moves a randomly created shape around the screen. The user moves the mouse to catch and click on the shape. The shape's speed and size can be varied. Keep statistics on how much time the user typically takes to catch a shape of a given size. The user will probably have more difficulty catching faster-moving, smaller shapes.
- 21.32 *(Calendar/Tickler File)* Using both audio and images, create a general-purpose calendar and

"tickler" file. For example, the program should sing "Happy Birthday" when you use it on your birthday. Have the program display images and play audios associated with important events. Also, have the program remind you in advance of these important events. It would be nice, for example, to have the program give you a week's notice so you can pick up an appropriate greeting card for that special person.

- 21.33 *(Rotating Images)* Create a Java program that lets you rotate an image through some number of degrees (out of a maximum of 360 degrees). The program should let you specify that you want to spin the image continuously. It should let you adjust the spin speed dynamically.
- 21.34 *(Coloring Black-and-White Photographs and Images)* Create a Java program that lets you paint a black-and-white photograph with color. Provide a color palette for selecting colors. Your program should let you apply different colors to different regions of the image.
- 21.35 *(Multimedia-Based Simpletron Simulator)* Modify the Simpletron simulator that you developed in the exercises in the previous chapters ([Exercise 7.34](#)[Exercise 7.36](#) and [Exercise 17.26](#)[Exercise 17.30](#)) to include multimedia features. Add computer-like sounds to indicate that the Simpletron is executing instructions. Add a breaking-glass sound when a fatal error occurs. Use flashing lights to indicate which cells of memory or which registers are currently being manipulated. Use other multimedia techniques, as appropriate, to make your Simpletron simulator more valuable to its users as an educational tool.

# Chapter 22. GUI Components: Part 2

*An actor entering through the door, you've got nothing. But if he enters through the window, you've got a situation.*

Billy Wilder

*... the force of events wakes slumberous talents.*

Edward Hoagland

*You and I would see more interesting photography if they would stop worrying, and instead, apply horsesense to the problem of recording the look and feel of their own era.*

Jessie Tarbox Beals

## OBJECTIVES

In this chapter you will learn:

- To create and manipulate sliders, menus, pop-up menus and windows.
- To change the look-and-feel of a GUI, using Swing's pluggable look-and-feel.
- To create a multiple-document interface with `JDesktopPane` and `JInternalFrame`.
- To use additional layout managers.

## Outline

[22.1](#) Introduction

[22.2](#) `JSlider`

[22.3](#) Windows: Additional Notes

[22.4](#) Using Menus with Frames

[22.5](#) `JPopupMenu`

## 22.1. Introduction

In this chapter, we continue our study of GUIs. We discuss additional components and layout managers and lay the groundwork for building more complex GUIs.

We begin our discussion with menus that enable the user to effectively perform tasks in the program. The look-and-feel of a Swing GUI can be uniform across all platforms on which a Java program executes, or the GUI can be customized by using Swing's [pluggable look-and-feel \(PLAF\)](#). We provide an example that illustrates how to change between Swing's default metal look-and-feel (which looks and behaves the same across platforms), a look-and-feel that simulates [Motif](#) (a popular UNIX look-and-feel) and one that simulates Microsoft's Windows look-and-feel.

Many of today's applications use a multiple-document interface (MDI) a main window (often called the parent window) containing other windows (often called child windows) to manage several open documents in parallel. For example, many e-mail programs allow you to have several e-mail windows open at the same time so that you can compose or read multiple e-mail messages. We demonstrate Swing's classes for creating multiple-document interfaces. The chapter finishes with a series of examples discussing additional layout managers for organizing graphical user interfaces.

Swing is a large and complex topic. There are many more GUI components and capabilities than can be presented here. Several more Swing GUI components are introduced in the remaining chapters of this book as they are needed. Our book *Advanced Java 2 Platform How to Program* discusses other, more advanced Swing components and capabilities.

## 22.2. JSlider

**JSlider**s enable the user to select from a range of integer values. Class **JSlider** inherits from **JComponent**. [Figure 22.1](#) shows a horizontal **JSlider** with **tick marks** and the **thumb** that allows the user to select a value. **JSliders** can be customized to display major tick marks, minor tick marks and labels for the tick marks. They also support **snap-to ticks**, which cause the thumb to snap to the closest tick mark when it is positioned between two tick marks.

Figure 22.1. **JSlider** component with horizontal orientation.

Most Swing GUI components support user interactions through the mouse and the keyboard. For example, if a **JSlider** has the focus (i.e., it is the currently selected GUI component in the user interface), the left arrow key and right arrow key cause the thumb of the **JSlider** to decrease or increase by 1, respectively. The down arrow key and up arrow key also cause the thumb of the **JSlider** to decrease or increase by 1 tick, respectively. The *PgDn* (page down) *key* and *PgUp* (page up) *key* cause the thumb of the **JSlider** to decrease or increase by **block increments** of one-tenth of the range of values, respectively. The *Home key* moves the thumb to the minimum value of the **JSlider**, and the *End key* moves the thumb to the maximum value of the **JSlider**.

**JSliders** have either a horizontal orientation or a vertical orientation. For a horizontal **JSlider**, the minimum value is at the left end of the **JSlider** and the maximum is at the right end. For a vertical **JSlider**, the minimum value is at the bottom and the maximum is at the top. The minimum and maximum value positions on a **JSlider** can be reversed by invoking **JSlider** method **setInverted** with **boolean** argument **true**. The relative position of the thumb indicates the current value of the **JSlider**.

The program in [Fig. 22.2](#), [Fig. 22.3](#) and [Fig. 22.4](#) allows the user to size a circle drawn on a subclass of **JPanel** called **OvalPanel** ([Fig. 22.2](#)). The user specifies the diameter of the circle with a horizontal **JSlider**. Class **OvalPanel** is a subclass of **JPanel** that knows how to draw a circle on itself, using its own instance variable **diameter** to determine the diameter of the circle. The **diameter** is used as the width and height of the bounding box in which the circle is displayed. The **diameter** value is set when the user interacts with the **JSlider**. The event handler calls method **setDiameter** in class **OvalPanel** to set the **diameter** and calls **repaint** to draw the new circle. The **repaint** call results in a call to **OvalPanel**'s **paintComponent** method.

Figure 22.2. **JPanel** subclass for drawing circles of a specified diameter.

8 import javax.swing.event.ChangeListener;
9 import javax.swing.event.ChangeEvent;
10
11 public class SliderFrame extends JFrame
12 {
13 private JSlider diameterJSlider; // slider to select diameter
14 private OvalPanel myPanel; // panel to draw circle
15
16 // no-argument constructor
17 public SliderFrame()
18 {
19 super ("Slider Demo");
20
21 myPanel = new OvalPanel(); // create panel to draw circle
22 myPanel.setBackground(Color.YELLOW); // set background to yellow
23
24 // set up JSlider to control diameter value
25 diameterJSlider =
26 new JSlider(SwingConstants.HORIZONTAL, 0, 200, 10);
27 diameterJSlider.setMajorTickSpacing(10); // create tick every 10
28 diameterJSlider.setPaintTicks(true); // paint ticks on slider
29
30 // register JSlider event listener
31 diameterJSlider.addChangeListener(
32
33 new ChangeListener() // anonymous inner class
34 {
35 // handle change in slider value
36 public void stateChanged(ChangeEvent e)
37 {
38 myPanel.setDiameter(diameterJSlider.getValue());
39 } // end method stateChanged
40 } // end anonymous inner class
41); // end call to addChangeListener
42
43 add(diameterJSlider, BorderLayout.SOUTH); // add slider to frame
44 add(myPanel, BorderLayout.CENTER); // add panel to frame
45 } // end SliderFrame constructor
46 } // end class SliderFrame

```

Figure 22.4. Test class for **SliderFrame**.

```

1 // Fig. 22.4: SliderDemo.java
2 // Testing SliderFrame.
3 import javax.swing.JFrame;
4
5 public class SliderDemo
6 {
7 public static void main(String args[])
8 {
9 SliderFrame sliderFrame = new SliderFrame();
10 sliderFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 sliderFrame.setSize(220, 270); // set frame size
12 sliderFrame.setVisible(true); // display frame
13 } // end main
14 } // end class SliderDemo

```

Class `OvalPanel` (Fig. 22.2) contains a `paintComponent` method (lines 1217) that draws a filled oval (a circle in this example), a `setDiameter` method (lines 2025) that changes the circle's `diameter` and `repaints` the `OvalPanel`, a `getPreferredSize` method (lines 2831) that returns the preferred width and height of an `OvalPanel` and a `getMinimumSize` method (lines 3437) that returns an `OvalPanel`'s minimum width and height.

## Look-and-Feel Observation 22.1

*If a new GUI component has a minimum width and height (i.e., smaller dimensions would render the component ineffective on the display), override method `getMinimumSize` to return the minimum width and height as an instance of class `Dimension`.*

## Software Engineering Observation 22.1

*For many GUI components, method `getMinimumSize` is implemented to return the result of a call to the component's `getPreferredSize` method.*

Class `SliderFrame` (Fig. 22.3) creates the `JSlider` that controls the diameter of the circle. Class `SliderFrame`'s constructor (lines 1745) creates `OvalPanel` object `myPanel` (line 21) and sets its background color (line 22). Lines 2526 create `JSlider` object `diameterSlider` to control the diameter of the circle drawn on the `OvalPanel`. The `JSlider` constructor takes four arguments. The first argument specifies the orientation of `diameterSlider`, which is `HORIZONTAL` (a constant in interface `SwingConstants`). The second and third arguments indicate the minimum and maximum integer values in the range of values for this `JSlider`. The last argument indicates that the initial value of the `JSlider` (i.e., where the thumb is displayed) should be 10.

---

[Page 1008]

Lines 2728 customize the appearance of the `JSlider`. Method `setMajorTick-Spacing` indicates that each major-tick mark represents 10 values in the range of values supported by the `JSlider`. Method `setPaintTicks` with a `true` argument indicates that the tick marks should be displayed (they are not displayed by default). For other methods that are used to customize a `JSlider`'s appearance, see the `JSlider` on-line documentation ([java.sun.com/j2se/5.0/docs/api/javawx/swing/JSlider.html](http://java.sun.com/j2se/5.0/docs/api/javawx/swing/JSlider.html)).

---

[Page 1009]

`JSliders` generate `ChangeEvents` (package `javax.swing.event`) in response to user interactions. An object of a class that implements interface `ChangeListener` (package `javax.swing.event`) and declares method `stateChanged` can respond to `ChangeEvents`. Lines 3141 register a `ChangeListener` to handle `diameterSlider`'s events. When method `stateChanged` (lines 3639) is called in response to a user interaction, line 38 calls `myPanel`'s `setDiameter` method and passes the current value of the `JSlider` as an argument. `JSlider` method `getValue` returns the current thumb position.

---

[Page 1010]

## 22.3. Windows: Additional Notes

In this section, we discuss several important `JFrame` issues. A `JFrame` is a [window](#) with a [title bar](#) and a [border](#). Class `JFrame` is a subclass of `java.awt.Frame` (which is a subclass of `java.awt.Window`). As such, `JFrame` is one of the few Swing GUI components that is not a lightweight GUI component. When you display a window from a Java program, the window is provided by the local platform's windowing toolkit, and therefore the window will look like every other window displayed on that platform. When a Java application executes on a Macintosh and displays a window, the window's title bar and borders will look like those of other Macintosh applications. When a Java application executes on a Microsoft Windows system and displays a window, the window's title bar and borders will look like those of other Microsoft Windows applications. And when a Java application executes on a Unix platform and displays a window, the window's title bar and borders will look like other Unix applications on that platform.

Class `JFrame` supports three operations when the user closes the window. By default, a window is hidden (i.e., removed from the screen) when the user closes it. This can be controlled with `JFrame` method `setDefaultCloseOperation`. Interface `WindowConstants` (package `javax.swing`), which class `JFrame` implements, declares three constants for use with this method: `DISPOSE_ON_CLOSE`, `DO_NOTHING_ON_CLOSE` and `HIDE_ON_CLOSE` (the default). Some platforms allow only a limited number of windows to be displayed on the screen. Thus, a window is a valuable resource that should be given back to the system when it is no longer needed. Class `Window` (an indirect superclass of `JFrame`) declares method `dispose` for this purpose. When a `Window` is no longer needed in an application, you should explicitly dispose of it. This can be done by calling the `Window`'s `dispose` method or by calling method `setDefaultCloseOperation` with the argument `WindowConstants.DISPOSE_ON_CLOSE`. Terminating an application will return window resources to the system. Setting the default close operation to `DO_NOTHING_ON_CLOSE` indicates that the program will determine what to do when the user indicates that the window should be closed.

### Good Programming Practice 22.1

*Windows are an expensive system resource. Return them to the system when they are no longer needed.*

By default, a window is not displayed on the screen until the program invokes the window's `setVisible` method (inherited from class `java.awt.Component`) with a `TRUE` argument. A window's size should be set with a call to method `setSize` (inherited from class `java.awt.Component`). The position of a window when it appears on the screen is specified with method `setLocation` (inherited from class `java.awt.Component`).

### Common Programming Error 22.1

*Forgetting to call method `setVisible` on a window is a runtime logic error; the window is not displayed.*

## Common Programming Error 22.2

*Forgetting to call the `setSize` method on a window is a runtime logic error only the title bar appears.*

When the user manipulates the window, this action generates **window events**. Event listeners are registered for window events with **Window** method **addWindowListener**. Interface **WindowListener** provides seven window-event-handling methods **windowActivated** (called when the user makes a window the active window), **windowClosed** (called after the window is closed), **windowClosing** (called when the user initiates closing of the window), **windowDeactivated** (called when the user makes another window the active window), **windowDeiconified** (called when the user restores a window from being minimized), **windowIconified** (called when the user minimizes a window) and **windowOpened** (called when a program first displays a window on the screen).

[< PREV](#)[NEXT >](#)

## 22.4. Using Menus with Frames

**Menus** are an integral part of GUIs. Menus allow the user to perform actions without unnecessarily cluttering a GUI with extra components. In Swing GUIs, menus can be attached only to objects of the classes that provide method `setJMenuBar`. Two such classes are `JFrame` and `JApplet`. The classes used to declare menus are `JMenuBar`, `JMenu`, `JMenuItem`, `JCheckBoxMenuItem` and class `JRadioButtonMenuItem`.

### Look-and-Feel Observation 22.2

*Menus simplify GUIs because components can be hidden within them. These components will only be visible when the user looks for them by selecting the menu.*

Class `JMenuBar` (a subclass of `JComponent`) contains the methods necessary to manage a **menu bar**, which is a container for menus. Class `JMenu` (a subclass of `javax.swing.JMenuItem`) contains the methods necessary for managing menus. Menus contain menu items and are added to menu bars or to other menus as submenus. When a menu is clicked, it expands to show its list of menu items.

Class `JMenuItem` (a subclass of `javax.swing.AbstractButton`) contains the methods necessary to manage **menu items**. A menu item is a GUI component inside a menu that, when selected, causes an action event. A menu item can be used to initiate an action or it can be a **submenu** that provides more menu items from which the user can select. Submenus are useful for grouping related menu items in a menu.

Class `JCheckBoxMenuItem` (a subclass of `javax.swing.JMenuItem`) contains the methods necessary to manage menu items that can be toggled on or off. When a `JCheckBoxMenuItem` is selected, a check appears to the left of the menu item. When the `JCheckBoxMenuItem` is selected again, the check is removed.

Class `JRadioButtonMenuItem` (a subclass of `javax.swing.JMenuItem`) contains the methods necessary to manage menu items that can be toggled on or off like `JCheckBoxMenuItems`. When multiple `JRadioButtonMenuItems` are maintained as part of a `ButtonGroup`, only one item in the group can be selected at a given time. When a `JRadioButtonMenuItem` is selected, a filled circle appears to the left of the menu item. When another `JRadioButtonMenuItem` is selected, the filled circle of the previously selected menu item is removed.

The application in [Fig. 22.5](#) and [Fig. 22.6](#) demonstrates various menu items. The application also demonstrates how to specify special characters called **mnemonics** that can provide quick access to a menu or menu item from the keyboard. Mnemonics can be used with all subclasses of `javax.swing.AbstractButton`.

Figure 22.5. **JMenus** and mnemonics.

Figure 22.6. Test class for **MenuFrame**.

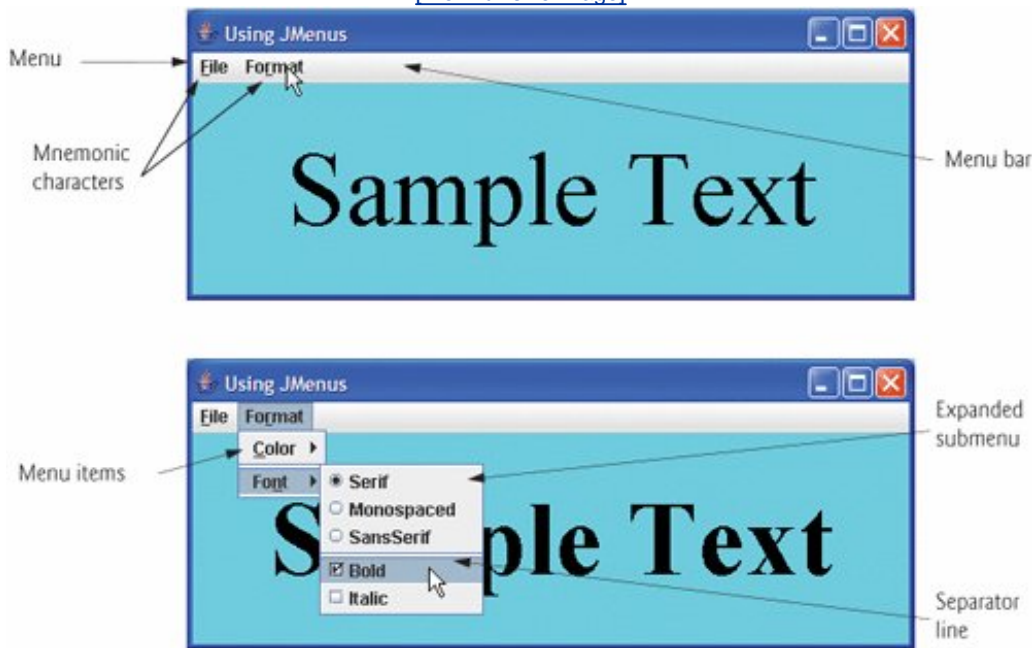

(This item is displayed on page 1017 in the print version)

```

1 // Fig. 22.6: MenuTest.java
2 // Testing MenuFrame.
3 import javax.swing.JFrame;
4
5 public class MenuTest
6 {
7 public static void main(String args[])
8 {
9 MenuFrame menuFrame = new MenuFrame(); // create MenuFrame
10 menuFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 menuFrame.setSize(500, 200); // set frame size
12 menuFrame.setVisible(true); // display frame
13 } // end main
14 } // end class MenuTest

```

[\[View full size image\]](#)

Class `MenuFrame` ([Fig. 22.5](#)) declares the GUI components and event handling for the menu items. Most of the code in this application appears in the class's constructor (lines 34151).

Lines 3876 set up the File menu and attach it to the menu bar. The File menu contains an About... menu item that displays a message dialog when the menu item is selected and an Exit menu item that can be selected to terminate the application.

Line 38 creates a `JMenu` and passes to the constructor the string "File" as the name of the menu. Line 39 uses `JMenu` method `setMnemonic` (inherited from class `AbstractButton`) to indicate that **F** is the mnemonic for this menu. Pressing the **Alt** key and the letter **F** opens the menu, just as clicking the menu name with the mouse would. In the GUI, the mnemonic character in the menu's name is displayed with an underline. (See the screen captures in [Fig. 22.6](#))

### Look-and-Feel Observation 22.3

*Mnemonics provide quick access to menu commands and button commands through the keyboard.*

### Look-and-Feel Observation 22.4

*Different mnemonics should be used for each button or menu item. Normally, the first letter in the label on the menu item or button is used as the mnemonic. If several buttons or menu items start with the same letter, choose the next most prominent letter in the name (e.g., **x** is commonly chosen for a button or menu item called *Exit*).*

Lines 4243 create `JMenuItem aboutItem` with the text "`About...`" and set its mnemonic to the letter `A`. This menu item is added to `fileMenu` at line 44 with `JMenu` method `add`. To access the `About...` menu item through the keyboard, press the `Alt` key and letter `F` to open the `File` menu, then press `A` to select the `About...` menu item. Lines 4756 create an `ActionListener` to process `aboutItem`'s action event. Lines 5254 display a message dialog box. In most prior uses of `showMessageDialog`, the first argument was `null`. The purpose of the first argument is to specify the `parent window` that helps determine where the dialog box will be displayed. If the parent window is specified as `null`, the dialog box appears in the center of the screen. Otherwise, it appears centered over the specified parent window. In this example, the program specifies the parent window with `MenuTest.this` the `this` reference of the `MenuTest` object. When using the `this` reference in an inner class, specifying `this` by itself refers to the inner-class object. To reference the outer-class object's `this` reference, qualify `this` with the outer-class name and a dot (`.`).

---

[Page 1018]

Dialog boxes are typically modal. A `modal dialog box` does not allow any other window in the application to be accessed until the dialog box is dismissed. The dialogs displayed with class `JOptionPane` are modal dialogs. Class `JDialog` can be used to create your own modal or nonmodal dialogs.

Lines 5972 create menu item `exitItem`, set its mnemonic to `x`, add it to `fileMenu` and register an `ActionListener` that terminates the application when the user selects `exitItem`.

Lines 7476 create the `JMenuBar`, attach it to the application window with `JFrame` method `setJMenuBar` and use `JMenuBar` method `add` to attach the `fileMenu` to the menu bar.

## Common Programming Error 22.3

*Forgetting to set the menu bar with `JFrame` method `setJMenuBar` results in the menu bar not being displayed on the `JFrame`.*

## Look-and-Feel Observation 22.5

*Menus appear left to right in the order that they are added to a `JMenuBar`.*

Lines 7879 create menu `formatMenu` and set its mnemonic to `r`. (`F` is not used because that is the `File` menu's mnemonic.)

Lines 8485 create menu `colorMenu` (this will be a submenu in the `Format` menu) and set its mnemonic to `C`. Line 88 creates `JRadioButtonMenuItem` array `colorItems`, which refers to the menu items in `colorMenu`. Line 89 creates `ButtonGroup` `colorGroup`, which will ensure that only one of the menu items in the `Color` submenu is selected at a time. Line 90 creates an instance of inner class `ItemHandler` (declared at lines 154181) that responds to selections from the `Color` and `Font` submenus (discussed shortly). The `for` statement at lines 93100 creates each `JRadioButtonMenuItem` in array `colorItems`, adds each menu item to `colorMenu` and to `colorGroup` and registers the `ActionListener` for each menu item.

Line 102 invokes `AbstractButton` method `setSelected` to select the first element in array `colorItems`. Line 104 adds `colorMenu` as a submenu of `formatMenu`. Line 105 invokes `JMenu` method `addSeparator` to add a horizontal `separator` line to the menu.

## Look-and-Feel Observation 22.6

*A submenu is created by adding a menu as a menu item in another menu. When the mouse is positioned over a submenu (or the submenu's mnemonic is pressed), the submenu expands to show its menu items.*

## Look-and-Feel Observation 22.7

*Separators can be added to a menu to group menu items logically.*

## Look-and-Feel Observation 22.8

*Any lightweight GUI component (i.e., a component that is a subclass of `JComponent`) can be added to a `JMenu` or to a `JMenuBar`.*

Lines 108126 create the `Font` submenu and several `JRadioButtonMenuItems` and select the first element of `JRadioButtonMenuItem` array `fonts`. Line 129 creates a `JCheckBoxMenuItem` array to represent the menu items for specifying bold and italic styles for the fonts. Line 130 creates an instance of inner class `StyleHandler` (declared at lines 184203) to respond to the `JCheckBoxMenuItem` events. The `for` statement at lines 133139 creates each `JCheckBoxMenuItem`, adds each menu item to `fontMenu` and registers the `ItemListener` for each menu item. Line 141 adds `fontMenu` as a submenu of `formatMenu`. Line 142 adds the `formatMenu` to bar (the menu bar).

Lines 145147 create a `JLabel` for which the `Format` menu items control the font, font color and font style.

The initial foreground color is set to the first element of array `colorValues` (`Color.BLACK`) by invoking `JComponent` method `setForeground`, and the initial font is set to `Serif` with `PLAIN` style and 72-point size. Line 149 sets the background color of the window's content pane to cyan, and line 150 attaches the `JLabel` to the `CENTER` of the content pane's `BorderLayout`.

`ItemHandler` method `actionPerformed` (lines 157-180) uses two `for` statements to determine which font or color menu item generated the event and sets the font or color of the `JLabel` `displayLabel`, respectively. The `if` condition at line 162 uses `AbstractButton` method `isSelected` to determine the selected `JRadioButtonMenuItem`. The `if` condition at line 172 invokes the event object's `getSource` method to get a reference to the `JRadioButtonMenuItem` that generated the event. Line 175 invokes `AbstractButton` method `getText` to obtain the name of the font from the menu item.

The program calls `StyleHandler` method `itemStateChanged` (lines 187-202) if the user selects a `JCheckBoxMenuItem` in the `fontMenu`. Lines 192 and 196 determine whether either or both of the `JCheckBoxMenuItems` are selected and use their combined state to determine the new style of the font.

[< PREV](#)[NEXT >](#)

## 22.5. JPopupMenu

Many of today's computer applications provide so-called [context-sensitive pop-up menus](#). In Swing, such menus are created with class `JPopupMenu` (a subclass of `JComponent`). These menus provide options that are specific to the component for which the [popup trigger event](#) was generated. On most systems, the pop-up trigger event occurs when the user presses and releases the right mouse button.

### Look-and-Feel Observation 22.9

*The pop-up trigger event is platform specific. On most platforms that use a mouse with multiple buttons, the pop-up trigger event occurs when the user clicks the right mouse button on a component that supports a pop-up menu.*

The application in [Figure 22.7](#) and [Fig. 22.8](#) creates a `JPopupMenu` that allows the user to select one of three colors and change the background color of the window. When the user clicks the right mouse button on the `PopupTest` window's background, a `JPopupMenu` containing colors appears. If the user clicks a `JRadioButtonMenuItem` for a color, `ItemHandler` method `actionPerformed` changes the background color of the window's content pane.

Figure 22.7. `JPopupMenu` for selecting colors.

(This item is displayed on pages 1020 - 1021 in the print version)

22 {

```

```

23 super("Using JPopupMenu");
24
25 ItemHandler handler = new ItemHandler(); // handler for menu items
26 String colors[] = { "Blue", "Yellow", "Red" }; // array of colors
27
28 ButtonGroup colorGroup = new ButtonGroup(); // manages color items
29 popupMenu = new JPopupMenu(); // create pop-up menu
30 items = new JRadioButtonMenuItem[3]; // items for selecting color
31
32 // construct menu item, add to popup menu, enable event handling
33 for (int count = 0; count < items.length; count++)
34 {
35 items[count] = new JRadioButtonMenuItem(colors[count]);
36 popupMenu.add(items[count]); // add item to pop-up menu
37 colorGroup.add(items[count]); // add item to button group
38 items[count].addActionListener(handler); // add handler
39 } // end for
40
41 setBackground(Color.WHITE); // set background to white
42
43 // declare a MouseListener for the window to display pop-up menu
44 addMouseListener(
45
46 new MouseAdapter() // anonymous inner class
47 {
48 // handle mouse press event
49 public void mousePressed(MouseEvent event)
50 {
51 checkForTriggerEvent(event); // check for trigger
52 } // end method mousePressed
53
54 // handle mouse release event
55 public void mouseReleased(MouseEvent event)
56 {
57 checkForTriggerEvent(event); // check for trigger
58 } // end method mouseReleased
59
60 // determine whether event should trigger popup menu
61 private void checkForTriggerEvent(MouseEvent event)
62 {
63 if (event.isPopupTrigger())
64 popupMenu.show(
65 event.getComponent(), event.getX(), event.getY());
66 } // end method checkForTriggerEvent
67 } // end anonymous inner class
68); // end call to addMouseListener
69 } // end PopupFrame constructor
70
71 // private inner class to handle menu item events
72 private class ItemHandler implements ActionListener
73 {
74 // process menu item selections
75 public void actionPerformed(ActionEvent event)
76 {
77 // determine which menu item was selected
78 for (int i = 0 ; i < items.length; i++)
79 {
80 if (event.getSource() == items[i])
81 {
82 getContentPane().setBackground(colorValues[i]);
83 return;

```

```

84 } // end if
85 } // end for
86 } // end method actionPerformed
87 } // end private inner class ItemHandler
88 } // end class PopupFrame

```

Figure 22.8. Test class for **PopupFrame**.

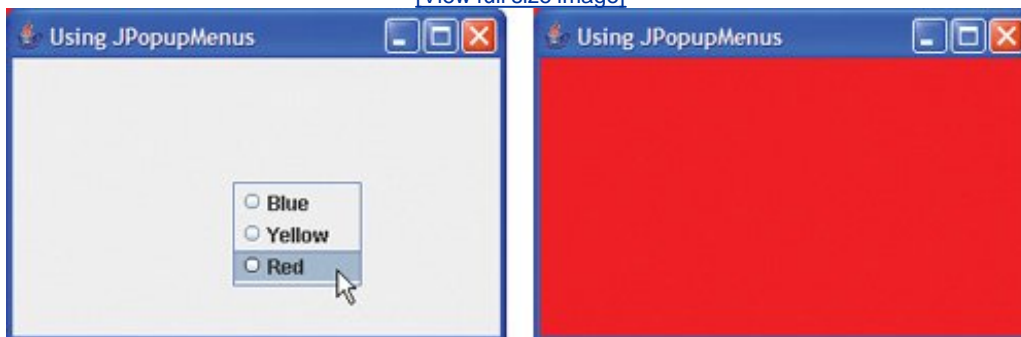

(This item is displayed on page 1022 in the print version)

```

1 // Fig. 22.8: PopupTest.java
2 // Testing PopupFrame.
3 import javax.swing.JFrame;
4
5 public class PopupTest
6 {
7 public static void main(String args[])
8 {
9 PopupFrame popupFrame = new PopupFrame(); // create PopupFrame
10 popupFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 popupFrame.setSize(300, 200); // set frame size
12 popupFrame.setVisible(true); // display frame
13 } // end main
14 } // end class PopupTest

```

[\[View full size image\]](#)

[Page 1021]

Line 25 of the **PopupFrame** constructor (lines 2169) creates an instance of class **ItemHandler** (declared in lines 7287) that will process the item events from the menu items in the pop-up menu. Line 29 creates the **JPopupMenu**. The **for** statement (lines 3339) creates a **JRadioButtonMenuItem** object (line 35), adds it to **popupMenu** (line 36), adds it to **ButtonGroup colorGroup** (line 37) to maintain one selected **JRadioButtonMenuItem** at a time and registers its **ActionListener** (line 38). Line 41 sets the initial background to white by invoking method **setBackground**.

Lines 4468 register a **MouseListener** to handle the mouse events of the application window. Methods **mousePressed** (lines 4952) and **mouseReleased** (lines 5558) check for the pop-up trigger event. Each method calls private utility method **checkForTriggerEvent** (lines 6166) to determine whether the pop-up trigger event occurred. If it did, **MouseEvent** method **isPopupTrigger** returns **TRUE**, and **JPopupMenu** method **show** displays the **JPopupMenu**. The first argument to method **show** specifies the **origin component**, whose

position helps determine where the `JPopupMenu` will appear on the screen. The last two arguments are the  $x$ - $y$  coordinates (measured from the origin component's upper-left corner) at which the `JPopupMenu` is to appear.

---

[Page 1022]

## Look-and-Feel Observation 22.10

*Displaying a `JPopupMenu` for the pop-up trigger event of multiple GUI components requires registering mouse-event handlers for each of those GUI components.*

When the user selects a menu item from the pop-up menu, class `ItemHandler`'s method `actionPerformed` (lines 7586) determines which `JRadioButtonMenuItem` the user selected and sets the background color of the window's content pane.

NEXT ▶

## 22.6. Pluggable Look-and-Feel

A program that uses Java's Abstract Window Toolkit GUI components (package `java.awt`) takes on the look-and-feel of the platform on which the program executes. A Java application running on a Macintosh looks like other applications running on a Macintosh. A Java application running on Microsoft Windows looks like other applications running on Microsoft Windows. A Java application running on a UNIX platform looks like other applications running on that UNIX platform. This is sometimes desirable, because it allows users of the application on each platform to use GUI components with which they are already familiar. However, it also introduces interesting portability issues.

---

 [Page 1023]

### Portability Tip 22.1

*GUI components look different on different platforms and may require different amounts of space to display. This could change their layout and alignments.*

### Portability Tip 22.2

*GUI components on different platforms have different default functionality (e.g., some platforms allow a button with the focus to be "pressed" with the space bar, and some do not).*

Swing's lightweight GUI components eliminate many of these issues by providing uniform functionality across platforms and by defining a uniform cross-platform look-and-feel (known as the [metal look-and-feel](#)). Swing also provides the flexibility to customize the look-and-feel to appear as a Microsoft Windows-style look-and-feel (on Window systems), a Motif-style (UNIX) look-and-feel (across all platforms) or a Macintosh look-and-feel (Mac systems).

The application in [Fig. 22.9](#) and [Fig. 22.10](#) demonstrates how to change the look-and-feel of a Swing GUI. The application creates several GUI components, so you can see the change in the look-and-feel of several GUI components at the same time. The first output window shows the standard metal look-and-feel, the second shows the Motif look-and-feel, and the third shows the Windows look-and-feel.

7 public static void main(String args[])
8 {
9 LookAndFeelFrame lookAndFeelFrame = new LookAndFeelFrame();
10 lookAndFeelFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 lookAndFeelFrame.setSize(300, 200); // set frame size
12 lookAndFeelFrame.setVisible(true); // display frame
13 } // end main
14 } // end class LookAndFeelDemo

```

[\[View full size image\]](#)

All the GUI components and event handling in this example have been covered before, so we concentrate on the mechanism for changing the look-and-feel in this example. Class **UIManager** (package `javax.swing`) contains nested class **LookAndFeelInfo** (a `public static` class) that maintains information about a look-and-feel. Line 22 declares an array of type `UIManager.LookAndFeelInfo` (note the syntax used to identify the inner class `LookAndFeelInfo`). Line 68 uses `UIManager` static method `getInstalledLookAndFeels` to get the array of `UIManager.LookAndFeelInfo` objects that describe each look-and-feel available on your system.

*Each look-and-feel is represented by a Java class. `UIManager` method `getInstalledLookAndFeels` does not load each class. Rather, it provides the names of the available look-and-feel classes so that a choice can be made (presumably once at program start-up). This reduces the overhead of having to load all the look-and-feel classes even if the program will not use some of them.*

Our utility method `changeTheLookAndFeel` (lines 7387) is called by the event handler for the `JRadioButtons` at the bottom of the user interface. The event handler (declared in `private` inner class `ItemHandler` at lines 90106) passes an integer representing the element in array `looks` that should be used to change the look-and-feel. Line 78 invokes `static` method `setLookAndFeel` of `UIManager` to change the look-and-feel. Method `getClassName` of class `UIManager.LookAndFeelInfo` determines the name of the look-and-feel class that corresponds to the `UIManager.LookAndFeelInfo` object. If the look-and-feel class is not already loaded, it will be loaded as part of the call to `setLookAndFeel`. Line 81 invokes `static` method `updateComponentTreeUI` of class `SwingUtilities` (package `javax.swing`) to change the look-and-feel of every GUI component attached to its argument (this instance of our application class `LookAndFeelDemo`) to the new look-and-feel.

## 22.7. JDesktopPane and JInternalFrame

Many of today's applications use a [multiple-document interface \(MDI\)](#) a main window (called the [parent window](#)) containing other windows (called [child windows](#)), to manage several open [documents](#) that are being processed in parallel. For example, many e-mail programs allow you to have several windows open at the same time, thso you can compose or read multiple e-mail messages simultaneously. Similarly, many word processors allow the user to open multiple documents in separate windows, making it possible to switch between them without having to close one to open another. The application in [Fig. 22.11](#) and [Fig. 22.12](#) demonstrates Swing's [JDesktopPane](#) and [JInternalFrame](#) classes for implementing multiple-document interfaces.

[\[View full size image\]](#)

Maximized internal frame

---

[Page 1028]

Lines 2733 create a `JMenuBar`, a `JMenu` and a `JMenuItem`, add the `JMenuItem` to the `JMenu`, add the `JMenu` to the `JMenuBar` and set the `JMenuBar` for the application window. When the user selects the `JMenuItem newFrame`, the application creates and displays a new `JInternalFrame` object containing an image.

Line 35 assigns `JDesktopPane` (package `javax.swing`) variable `theDesktop` a new `JDesktopPane` object that will be used to manage the `JInternalFrame` child windows. Line 36 adds the `JDesktopPane` to the `JFrame`. By default, the `JDesktopPane` is added to the center of the content pane's `BorderLayout`, so the `JDesktopPane` expands to fill the entire application window.

---

[Page 1029]

Lines 3958 register an `ActionListener` to handle the event when the user selects the `newFrame` menu item. When the event occurs, method `actionPerformed` (lines 4456) creates a `JInternalFrame` object in lines 4748. The `JInternalFrame` constructor used here takes five arguments: a string for the title bar of the internal window, a `boolean` indicating whether the internal frame can be resized by the user, a `boolean` indicating whether the internal frame can be closed by the user, a `boolean` indicating whether the internal frame can be maximized by the user and a `boolean` indicating whether the internal frame can be minimized by the user. For each of the `boolean` arguments, a `true` value indicates that the operation should be allowed (as is the case here).

---

[Page 1030]

As with `JFrames` and `JApplets`, a `JInternalFrame` has a content pane to which GUI components can be attached. Line 50 creates an instance of our class `MyJPanel` (declared at lines 6390) that is added to the `JInternalFrame` at line 51.

Line 52 uses `JInternalFrame` method `pack` to set the size of the child window. Method `pack` uses the preferred sizes of the components to determine the window's size. Class `MyJPanel` declares method `getPreferredSize` (lines 8589) to specify the panel's preferred size for use by the `pack` method. Line 54

adds the `JInternalFrame` to the `JDesktopPane`, and line 55 displays the `JInternalFrame`.

Classes `JInternalFrame` and `JDesktopPane` provide many methods for managing child windows. See the `JInternalFrame` and `JDesktopPane` online API documentation for complete lists of these methods:

## 22.8. JTabbedPane

A `JTabbedPane` arranges GUI components into layers in which only one layer is visible at a time. Users access each layer via a tabsimilar to folders in a file cabinet. When the user clicks a tab, the appropriate layer is displayed. The tabs appear at the top by default but also can be positioned at the left, right or bottom of the `JTabbedPane`. Any component can be placed on a tab. If the component is a container, such as a panel, it can use any layout manager to lay out several components on the tab. Class `JTabbedPane` is a subclass of `JComponent`. The application in [Fig. 22.13](#) and [Fig. 22.14](#) creates one tabbed pane with three tabs. Each tab displays one of the `JPanel`s `panell1`, `panel2` or `panel3`.

Figure 22.13. `JTabbedPane` used to organize GUI components.

```
1 // Fig. 22.13: JTabbedPaneFrame.java
2 // Demonstrating JTabbedPane.

9 import javax.swing.JButton;
10 import javax.swing.SwingConstants;
11
12 public class JTabbedPaneFrame extends JFrame
13 {
14 // set up GUI
15 public JTabbedPaneFrame()
16 {
17 super("JTabbedPane Demo ");
18
19 JTabbedPane tabbedPane = new JTabbedPane(); // create JTabbedPane
20
21 // set up panell1 and add it to JTabbedPane
22 JLabel label1 = new JLabel("panel one", SwingConstants.CENTER);
23 JPanel panell1 = new JPanel(); // create first panel
24 panell1.add(label1); // add label to panel
25 tabbedPane.addTab("Tab One", null, panell1, "First Panel");
26
27 // set up panel2 and add it to JTabbedPane
28 JLabel label2 = new JLabel("panel two", SwingConstants.CENTER);
29 JPanel panel2 = new JPanel(); // create second panel
30 panel2.setBackground(Color.YELLOW); // set background to yellow
31 panel2.add(label2); // add label to panel
32 tabbedPane.addTab("Tab Two", null, panel2, "Second Panel");
33
34 // set up panel3 and add it to JTabbedPane
35 JLabel label3 = new JLabel("panel three");
36 JPanel panel3 = new JPanel(); // create third panel
37 panel3.setLayout(new BorderLayout()); // use borderlayout
38 panel3.add(new JButton("North"), BorderLayout.NORTH);
```

```

39 panel3.add(new JButton("West"), BorderLayout.WEST);
40 panel3.add(new JButton("East"), BorderLayout.EAST);
41 panel3.add(new JButton("South"), BorderLayout.SOUTH);
42 panel3.add(label3, BorderLayout.CENTER);
43 tabbedPane.addTab("Tab Three", null, panel3, "Third Panel");
44
45 add(tabbedPane); // add JTabbedPane to frame
46 } // end JTabbedPaneFrame constructor
47 } // end class JTabbedPaneFrame

```

[Page 1032]

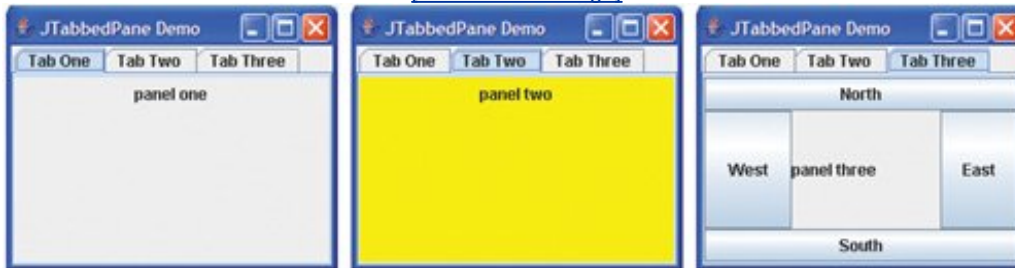

Figure 22.14. Test class for **JTabbedPaneFrame**.

```

2 // Demonstrating JTabbedPane.
3 import javax.swing.JFrame;
4
5 public class JTabbedPaneDemo
6 {
7 public static void main(String args[])
8 {
9 JTabbedPaneFrame tabbedPaneFrame = new JTabbedPaneFrame();
10 tabbedPaneFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 tabbedPaneFrame.setSize(250, 200); // set frame size
12 tabbedPaneFrame.setVisible(true); // display frame
13 } // end main
14 } // end class JTabbedPaneDemo

```

[\[View full size image\]](#)

The constructor (lines 1546) builds the GUI. Line 19 creates an empty **JTabbedPane** with default settings that is, tabs across the top. If the tabs do not fit on one line, they will wrap to form additional lines of tabs. Next the constructor creates the **JPanels** **panel1**, **panel2** and **panel3** and their GUI components. As we set up each panel, we add it to **tabbedPane**, using **JTabbedPane** method **addTab** with four arguments. The first argument is a string that specifies the title of the tab. The second argument is an **Icon** reference that specifies an icon to display on the tab. If the **Icon** is a **null** reference, no image is displayed. The third argument is a **Component** reference that represents the GUI component to display when the user clicks the tab. The last argument is a string that specifies the tool tip for the tab. For example, line 25 adds **JPanel** **panel1** to **tabbedPane** with title "Tab One" and the tool tip "First Panel". **JPanels** **panel2** and **panel3** are added to **tabbedPane** at lines 32 and 43. To view a tab, click it with the mouse or use the arrow keys to cycle through the tabs.

## 22.9. Layout Managers: **BoxLayout** and **GridBagLayout**

In [Chapter 11](#), we introduced three layout managers `FlowLayout`, `BorderLayout` and `GridLayout`. This section presents two additional layout managers (summarized in [Fig. 22.15](#)). We discuss these layout managers in the examples that follow.

Figure 22.15. Additional layout managers.

(This item is displayed on page 1033 in the print version)

| Layout Manager             | Description                                                                                                                                                                                                                                                                                                                                  |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>BoxLayout</code>     | A layout manager that allows GUI components to be arranged left-to-right or top-to-bottom in a container. Class <code>Box</code> declares a container with <code>BoxLayout</code> as its default layout manager and provides <code>static</code> methods to create a <code>Box</code> with a horizontal or vertical <code>BoxLayout</code> . |
| <code>GridBagLayout</code> | A layout manager similar to <code>GridLayout</code> , but unlike it in that components can vary in size and can be added in any order.                                                                                                                                                                                                       |

### **BoxLayout** Layout Manager

The `BoxLayout` layout manager (in package `javax.swing`) arranges GUI components horizontally along a container's *x*-axis or vertically along its *y*-axis. The application in [Fig. 22.16](#) and [Fig. 22.17](#) demonstrates `BoxLayout` and the container class `Box` that uses `BoxLayout` as its default layout manager.

Figure 22.16. **BoxLayout** layout manager.

(This item is displayed on pages 1033 - 1034 in the print version)

```
1 // Fig. 22.16: BoxLayoutFrame.java
2 // Demonstrating BoxLayout.
3 import java.awt.Dimension;
4 import javax.swing.JFrame;
5 import javax.swing.Box;
6 import javax.swing.JButton;
7 import javax.swing.BoxLayout;
8 import javax.swing.JPanel;
9 import javax.swing.JTabbedPane;
10
11 public class BoxLayoutFrame extends JFrame
12 {
13 // set up GUI
14 public BoxLayoutFrame()
15 {
16 super("Demonstrating BoxLayout");
```

```

17
18 // create Box containers with BoxLayout
19 Box horizontal1 = Box.createHorizontalBox();
20 Box vertical1 = Box.createVerticalBox();
21 Box horizontal2 = Box.createHorizontalBox();
22 Box vertical2 = Box.createVerticalBox();
23
24 final int SIZE = 3; // number of buttons on each Box
25
26 // add buttons to Box horizontal1
27 for (int count = 0; count < SIZE; count++)
28 horizontal1.add(new JButton("Button " + count));
29
30 // create strut and add buttons to Box vertical1
31 for (int count = 0; count < SIZE; count++)
32 {
33 vertical1.add(Box.createVerticalStrut(25));
34 vertical1.add(new JButton("Button " + count));
35 } // end for
36
37 // create horizontal glue and add buttons to Box horizontal2
38 for (int count = 0; count < SIZE; count++)
39 {
40 horizontal2.add(Box.createHorizontalGlue());
41 horizontal2.add(new JButton("Button " + count));
42 } // end for
43
44 // create rigid area and add buttons to Box vertical2
45 for (int count = 0; count < SIZE; count++)
46 {
47 vertical2.add(Box.createRigidArea(new Dimension(12, 8)));
48 vertical2.add(new JButton("Button " + count));
49 } // end for
50
51 // create vertical glue and add buttons to panel
52 JPanel panel = new JPanel();
53 panel.setLayout(new BoxLayout(panel, BoxLayout.Y_AXIS));
54
55 for (int count = 0; count < SIZE; count++)
56 {
57 panel.add(Box.createGlue());
58 panel.add(new JButton("Button " + count));
59 } // end for
60
61 // create a JTabbedPane
62 JTabbedPane tabs = new JTabbedPane(
63 JTabbedPane.TOP, JTabbedPane.SCROLL_TAB_LAYOUT);
64
65 // place each container on tabbed pane
66 tabs.addTab("Horizontal Box", horizontal1);
67 tabs.addTab("Vertical Box with Struts", vertical1);
68 tabs.addTab("Horizontal Box with Glue", horizontal2);
69 tabs.addTab("Vertical Box with Rigid Areas", vertical2);
70 tabs.addTab("Vertical Box with Glue", panel);
71
72 add(tabs); // place tabbed pane on frame
73 } // end BoxLayoutFrame constructor
74 } // end class BoxLayoutFrame

```

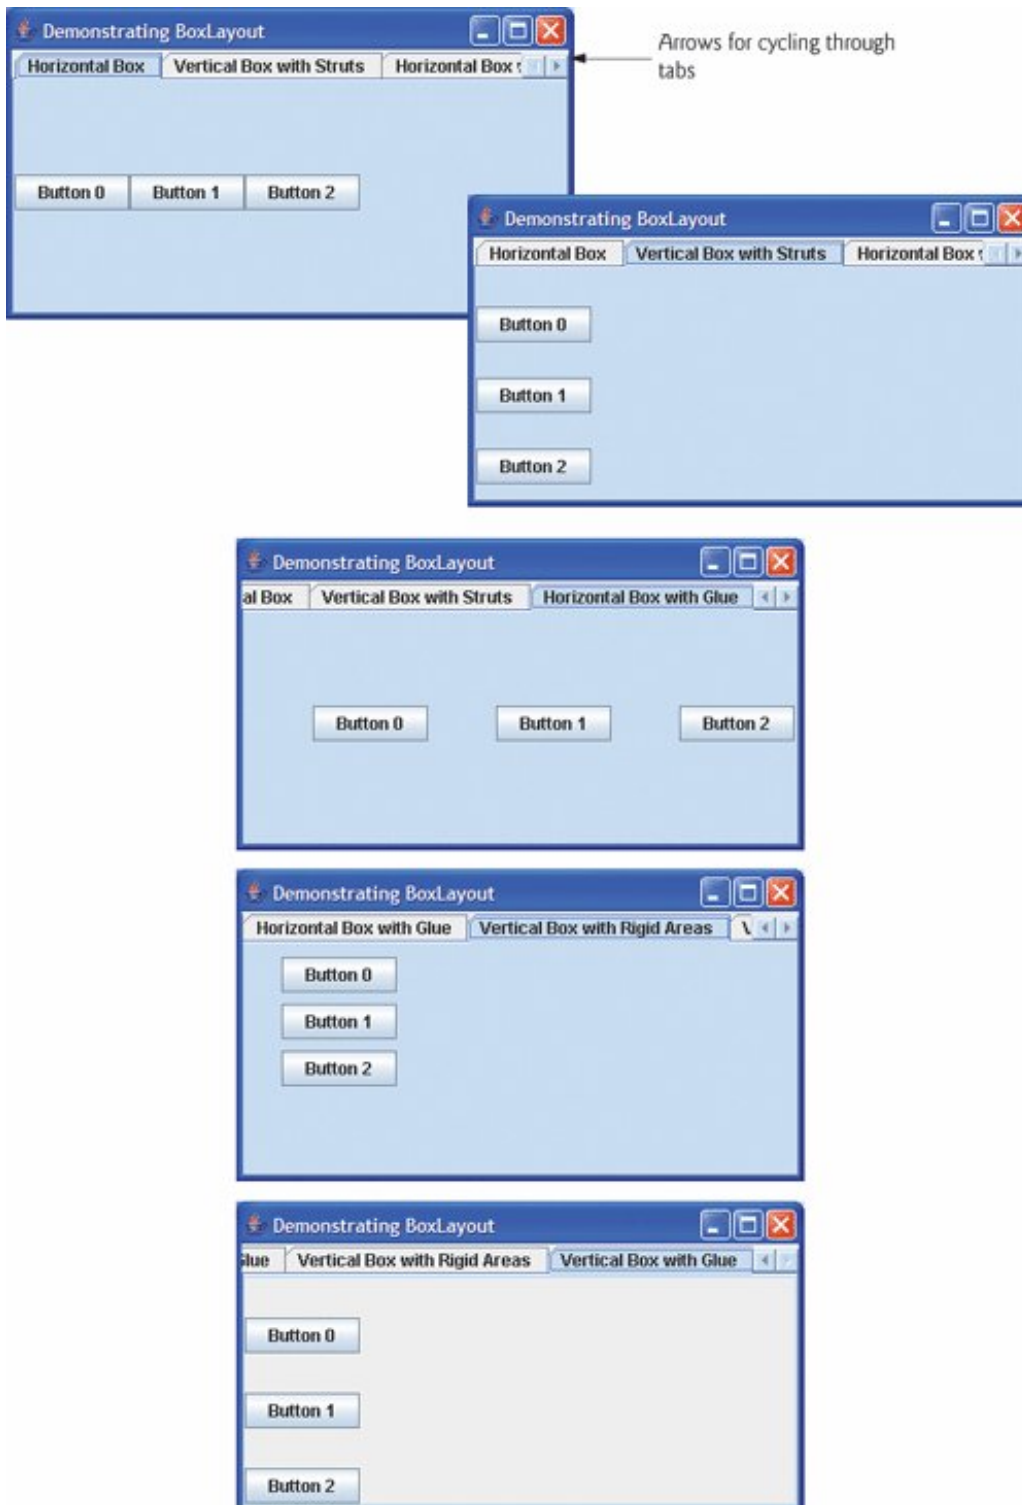

Figure 22.17. Test class for **BoxLayoutFrame**.

(This item is displayed on pages 1035 - 1036 in the print version)

```
1 // Fig. 22.17: BoxLayoutDemo.java
2 // Demonstrating BoxLayout.
3 import javax.swing.JFrame;
4
5 public class BoxLayoutDemo
6 {
7 public static void main(String args[])
8 {
9 BoxLayoutFrame boxLayoutFrame = new BoxLayoutFrame();
10 boxLayoutFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 boxLayoutFrame.setSize(400, 220); // set frame size
12 boxLayoutFrame.setVisible(true); // display frame
13 } // end main
14 } // end class BoxLayoutDemo
```

[\[View full size image\]](#)

Lines 1922 create `Box` containers. References `horizontal1` and `horizontal2` are initialized with `static Box` method `createHorizontalBox`, which returns a `Box` container with a horizontal `BoxLayout` in which GUI components are arranged left-to-right. Variables `vertical1` and `vertical2` are initialized with `static Box` method `createVerticalBox`, which returns references to `Box` containers with a vertical `BoxLayout` in which GUI components are arranged top-to-bottom.

The `for` statement at lines 2728 adds three `JButtons` to `horizontal1`. The `for` statement at lines 3135 adds three `JButtons` to `vertical1`. Before adding each button, line 33 adds a `vertical strut` to the container with `static Box` method `createVerticalStrut`. A vertical strut is an invisible GUI component that has a fixed pixel height and is used to guarantee a fixed amount of space between GUI components. The `int` argument

to method `createVerticalStrut` determines the height of the strut in pixels. When the container is resized, the distance between GUI components separated by struts does not change. Class `Box` also declares method `createHorizontalStrut` for horizontal `BoxLayouts`.

---

[Page 1035]

The `for` statement at lines 3842 adds three `JButtons` to `horizontal2`. Before adding each button, line 40 adds `horizontal glue` to the container with `static Box` method `createHorizontalGlue`. Horizontal glue is an invisible GUI component that can be used between fixed-size GUI components to occupy additional space. Normally, extra space appears to the right of the last horizontal GUI component or below the last vertical one in a `BoxLayout`. Glue allows the extra space to be placed between GUI components. When the container is resized, components separated by glue components remain the same size, but the glue stretches or contracts to occupy the space between them. Class `Box` also declares method `createVerticalGlue` for vertical `BoxLayouts`.

The `for` statement at lines 4549 adds three `JButtons` to `vertical2`. Before each button is added, line 47 adds a `rigid area` to the container with `static Box` method `createRigidArea`. A rigid area is an invisible GUI component that always has a fixed pixel width and height. The argument to method `createRigidArea` is a `Dimension` object that specifies the area's width and height.

---

[Page 1036]

Lines 5253 create a `JPanel` object and set its layout to a `BoxLayout` in the conventional manner, using `Container` method `setLayout`. The `BoxLayout` constructor receives a reference to the container for which it controls the layout and a constant indicating whether the layout is horizontal (`BoxLayout.X_AXIS`) or vertical (`BoxLayout.Y_AXIS`).

The `for` statement at lines 5559 adds three `JButtons` to `panel`. Before adding each button, line 57 adds a glue component to the container with `static Box` method `create-Glue`. This component expands or contracts based on the size of the `Box`.

Lines 6263 create a `JTabbedPane` to display the five containers in this program. The argument `JTabbedPane.TOP` sent to the constructor indicates that the tabs should appear The argument `JTabbedPane.SCROLL_TAB_LAYOUT` specifies that the tabs should scroll if there are too many tabs to fit on one line.

The `Box` containers and the `JPanel` are attached to the `JTabbedPane` at lines 6670. Try executing the application. When the window appears, resize the window to see how the glue components, strut components and rigid area affect the layout on each tab.

---

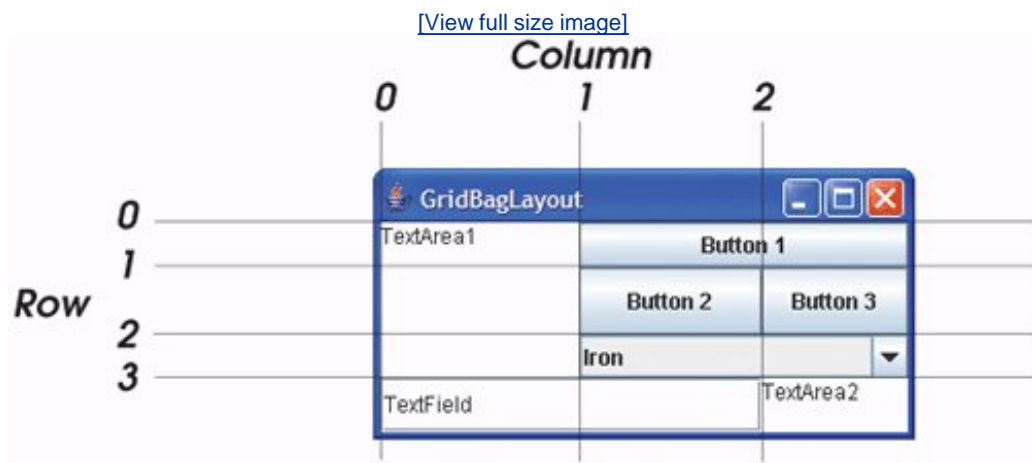

[Page 1037]

## **GridBagLayout** Layout Manager

The most complex and most powerful of the predefined layout managers is `GridBagLayout` (in package `java.awt`). This layout is similar to `GridLayout` in that it arranges components in a grid. However, `GridBagLayout` is more flexible. The components can vary in size (i.e., they can occupy multiple rows and columns) and can be added in any order.

The first step in using `GridBagLayout` is determining the appearance of the GUI. For this step you need only a piece of paper. Draw the GUI and then draw a grid over it, dividing the components into rows and columns. The initial row and column numbers should be 0, so that the `GridBagLayout` layout manager can use the row and column number to properly place the components in the grid. [Figure 22.18](#) demonstrates drawing the lines for the rows and columns over a GUI.

Figure 22.18. Designing a GUI that will use `GridBagLayout`.

A `GridBagConstraints` object describes how a component is placed in a `GridBagLayout`. Several `GridBagConstraints` fields are summarized in [Fig. 22.19](#).

Figure 22.19. `GridBagConstraints` fields.

(This item is displayed on page 1038 in the print version)

| <code>GridBagConstraints</code> field | Description                                                                                                                                                                                                                                                                                      |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>anchor</code>                   | Specifies the relative position ( <code>NORTH</code> , <code>NORTHEAST</code> , <code>EAST</code> , <code>SOUTHEAST</code> , <code>SOUTH</code> , <code>SOUTHWEST</code> , <code>WEST</code> , <code>NORTHWEST</code> , <code>CENTER</code> ) of the component in an area that it does not fill. |
| <code>fill</code>                     | Resizes the component in specified direction ( <code>NONE</code> , <code>HORIZONTAL</code> , <code>VERTICAL</code> , <code>BOTH</code> ) when the display area is larger than the component.                                                                                                     |
| <code>gridx</code>                    | The column in which the component will be placed.                                                                                                                                                                                                                                                |
| <code>gridy</code>                    | The row in which the component will be placed.                                                                                                                                                                                                                                                   |
| <code>gridwidth</code>                | The number of columns the component occupies.                                                                                                                                                                                                                                                    |
| <code>gridheight</code>               | The number of rows the component occupies.                                                                                                                                                                                                                                                       |
| <code>weightx</code>                  | The amount of extra space to allocate horizontally. The grid slot can become wider when extra space is available.                                                                                                                                                                                |
| <code>weighty</code>                  | The amount of extra space to allocate vertically. The grid slot can become taller when extra space is available.                                                                                                                                                                                 |

`GridBagConstraints` field `anchor` specifies the relative position of the component in an area that it does not fill. The variable `anchor` is assigned one of the following `GridBagConstraints` constants: `NORTH`, `NORTHEAST`, `EAST`, `SOUTHEAST`, `SOUTH`, `SOUTHWEST`, `WEST`, `NORTHWEST` or `CENTER`. The default value is `CENTER`.

`GridBagConstraints` field `fill` defines how the component grows if the area in which it can be displayed is larger than the component. The variable `fill` is assigned one of the following `GridBagConstraints` constants: `NONE`, `VERTICAL`, `HORIZONTAL` or `BOTH`. The default value is `NONE`, which indicates that the component will not grow in either direction. `VERTICAL` indicates that it will grow vertically. `HORIZONTAL` indicates that the component will grow horizontally. `BOTH` indicates that it will grow in both directions.

Variables `gridx` and `gridy` specify where the upper-left corner of the component is placed in the grid.

Variable `gridx` corresponds to the column, and variable `gridy` corresponds to the row. In [Fig. 22.18](#), the `JComboBox` (displaying "Iron") has a `gridx` value of 1 and a `gridy` value of 2.

Variable `gridwidth` specifies the number of columns a component occupies. The `JComboBox` occupies two columns. Variable `gridheight` specifies the number of rows a component occupies. The `JTextArea` on the left side of [Fig. 22.18](#) occupies three rows.

Variable `weightx` specifies how to distribute extra horizontal space to grid slots in a `GridBagLayout` when the container is resized. A zero value indicates that the grid slot does not grow horizontally on its own. However, if the component spans a column containing a component with nonzero `weightx` value, the component with zero `weightx` value will grow horizontally in the same proportion as the other component(s) in the same column. This is because each component must be maintained in the same row and column in which it was originally placed.

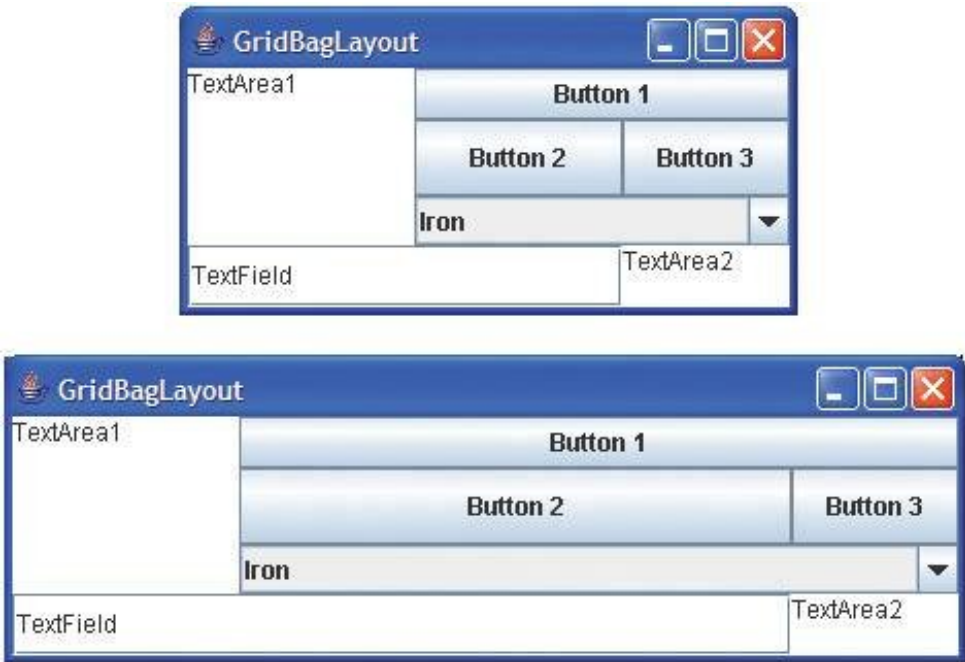

Variable `weighty` specifies how to distribute extra vertical space to grid slots in a `GridBagLayout` when the container is resized. A zero value indicates that the grid slot does not grow vertically on its own. However, if the component spans a row containing a component with nonzero `weighty` value, the component with zero `weighty` value grows vertically in the same proportion as the other component(s) in the same row.

In [Fig. 22.18](#), the effects of `weighty` and `weightx` cannot easily be seen until the container is resized and additional space becomes available. Components with larger weight values occupy more of the additional space than those with smaller weight values.

Components should be given nonzero positive weight values otherwise they will "huddle" together in the middle of the container. [Figure 22.20](#) shows the GUI of [Fig. 22.18](#) with all weights set to zero.

Figure 22.20. `GridBagLayout` with the weights set to zero.

(This item is displayed on page 1039 in the print version)

The application in [Fig. 22.21](#) and [Fig. 22.22](#) uses the `GridBagLayout` layout manager to arrange the components of the GUI in [Fig. 22.18](#). The application does nothing except demonstrate how to use `GridBagLayout`.

Figure 22.21. **GridBagLayout** layout manager.

12 gridBagFrame.setVisible(true); // display frame
13 } // end main
14 } // end class GridBagDemo

```

The GUI consists of three `JButtons`, two `JTextAreas`, a `JComboBox` and a `JTextField`. The layout manager for the content pane is `GridBagLayout`. Lines 2122 create the `GridBagLayout` object and set the layout manager for the `JFrame` to `layout`. Line 23 creates the `GridBagConstraints` object used to determine the location and size of each component in the grid. Lines 2635 create each GUI component that will be added to the content pane.

[Page 1039]

Lines 3940 configure `JTextArea textArea1` and add it to the content pane. The values for `weightx` and `weighty` values are not specified in `constraints`, so each has the value zero by default. Thus, the `JTextArea` will not resize itself even if space is available. However, it spans multiple rows, so the vertical size is subject to the `weighty` values of `JButtons button2` and `button3`. When either button is resized vertically based on its `weighty` value, the `JTextArea` is also resized.

[Page 1041]

Line 39 sets variable `fill` in `constraints` to `GridBagConstraints.BOTH`, causing the `JTextArea` to always fill its entire allocated area in the grid. An `anchor` value is not specified in `constraints`, so the default `CENTER` is

used. We do not use variable anchor in this application, so all the components will use the default. Line 40 calls our utility method `addComponent` (declared at lines 6978). The `JTextArea` object, the row, the column, the number of columns to span and the number of rows to span are passed as arguments.

`JButton button1` is the next component added (lines 4344). By default, the `weightx` and `weighty` values are still zero. The `fill` variable is set to `HORIZONTAL` the component will always fill its area in the horizontal direction. The vertical direction is not filled. The `weighty` value is zero, so the button will become taller only if another component in the same row has a nonzero `weighty` value. `JButton button1` is located at row 0, column 1. One row and two columns are occupied.

`JComboBox comboBox` is the next component added (line 48). By default, the `weightx` and `weighty` values are zero, and the `fill` variable is set to `HORIZONTAL`. The `JComboBox` button will grow only in the horizontal direction. Note that the `weightx`, `weighty` and `fill` variables retain the values set in `constraints` until they are changed. The `JComboBox` button is placed at row 2, column 1. One row and two columns are occupied.

`JButton button2` is the next component added (lines 5154). It is given a `weightx` value of 1000 and a `weighty` value of 1. The area occupied by the button is capable of growing in the vertical and horizontal directions. The `fill` variable is set to `BOTH`, which specifies that the button will always fill the entire area. When the window is resized, `button2` will grow. The button is placed at row 1, column 1. One row and one column are occupied.

`JButton button3` is added next (lines 5759). Both the `weightx` value and `weighty` value are set to zero, and the value of `fill` is `BOTH`. `JButton button3` will grow if the window is resized it is affected by the weight values of `button2`. Note that the `weightx` value for `button2` is much larger than that for `button3`. When resizing occurs, `button2` will occupy a larger percentage of the new space. The button is placed at row 1, column 2. One row and one column are occupied.

Both the `JTextField textField` (line 62) and `JTextArea textArea2` (line 65) have a `weightx` value of 0 and a `weighty` value of 0. The value of `fill` is `BOTH`. The `JTextField` is placed at row 3, column 0, and the `JTextArea` at row 3, column 2. The `JTextField` occupies one row and two columns, the `JTextArea` one row and one column.

Method `addComponent`'s parameters are a `Component` reference `component` and integers `row`, `column`, `width` and `height`. Lines 7273 set the `GridBagConstraints` variables `gridx` and `gridy`. The `gridx` variable is assigned the column in which the `Component` will be placed, and the `gridy` value is assigned the row in which the `Component` will be placed. Lines 7475 set the `GridBagConstraints` variables `gridwidth` and `gridheight`. The `gridwidth` variable specifies the number of columns the `Component` will span in the grid, and the `gridheight` variable specifies the number of rows the `Component` will span in the grid. Line 76 sets the `GridBagConstraints` for a component in the `GridBagLayout`. Method `setConstraints` of class `GridBagLayout` takes a `Component` argument and a `GridBagConstraints` argument. Line 77 adds the component to the `JFrame`.

When you execute this application, try resizing the window to see how the constraints for each GUI component affect its position and size in the window.

## **GridBagConstraints Constants `RELATIVE` and `REMAINDER`**

Instead of `gridx` and `gridy`, a variation of `GridBagLayout` uses `GridBagConstraints` constants `RELATIVE` and `REMAINDER`. `RELATIVE` specifies that the next-to-last component in a particular row should be placed to the right of the previous component in the row. `REMAINDER` specifies that a component is the last component in a row. Any component that is not the second-to-last or last component on a row must specify values for `GridBagConstraints` variables `gridwidth` and `gridheight`. The application in [Fig. 22.23](#) and [Fig. 22.24](#) arranges components in `GridBagLayout`, using these constants.

Figure 22.23. **GridBagConstraints** constants **RELATIVE** and **REMAINDER**.

(This item is displayed on pages 1043 - 1044 in the print version)

```

```

56 constraints.gridwidth = GridBagConstraints.REMAINDER;
57 addComponent(buttons[2]);
58
59 // comboBox -- weightx is 1: fill is BOTH
60 constraints.weighty = 0;
61 constraints.gridwidth = GridBagConstraints.REMAINDER;
62 addComponent(comboBox);
63
64 // buttons[3] -- weightx is 1: fill is BOTH
65 constraints.weighty = 1;
66 constraints.gridwidth = GridBagConstraints.REMAINDER;
67 addComponent(buttons[3]);
68
69 // buttons[4] -- weightx and weighty are 1: fill is BOTH
70 constraints.gridwidth = GridBagConstraints.RELATIVE;
71 addComponent(buttons[4]);
72
73 // list -- weightx and weighty are 1: fill is BOTH
74 constraints.gridwidth = GridBagConstraints.REMAINDER;
75 addComponent(list);
76 } // end GridBagFrame2 constructor
77
78 // add a component to the container
79 private void addComponent(Component component)
80 {
81 layout.setConstraints(component, constraints);
82 add(component); // add component
83 } // end method addComponent
84 } // end class GridBagFrame2

```

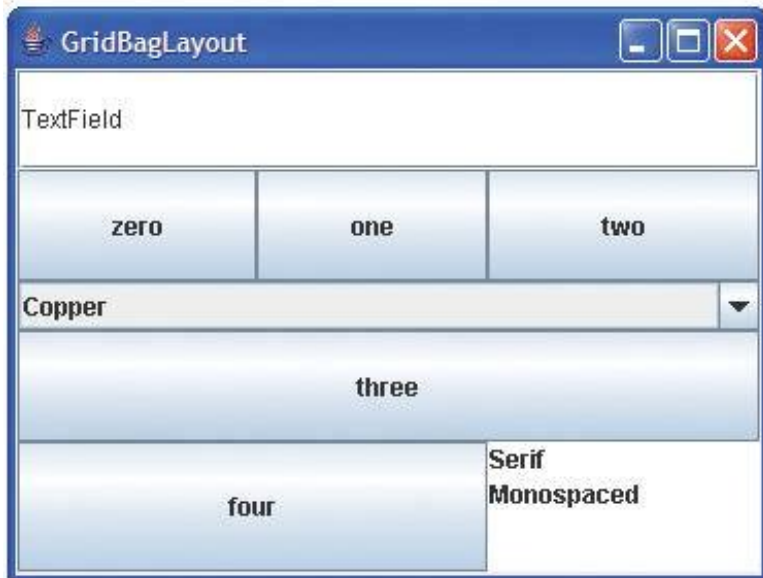

Figure 22.24. Test class for **GridBagDemo2**.

(This item is displayed on page 1045 in the print version)

```

1 // Fig. 22.24: GridBagDemo2.java
2 // Demonstrating GridBagLayout constants.
3 import javax.swing.JFrame;
4
5 public class GridBagDemo2
6 {
7 public static void main(String args[])
8 {
9 GridBagFrame2 gridBagFrame = new GridBagFrame2();
10 gridBagFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 gridBagFrame.setSize(300, 200); // set frame size
12 gridBagFrame.setVisible(true); // display frame
13 } // end main
14 } // end class GridBagDemo2

```

Lines 2122 create a `GridBagLayout` and use it to set the `JFrame`'s layout manager. The components that are placed in `GridBagLayout` are created in lines 2738 they are a `JComboBox`, a `JTextField`, a `JList` and five `JButtons`.

The `JTextField` is added first (lines 4145). The `weightx` and `weighty` values are set to 1. The `fill` variable is set to `BOTH`. Line 44 specifies that the `JTextField` is the last component on the line. The `JTextField` is added to the content pane with a call to our utility method `addComponent` (declared at lines 7983). Method `addComponent` takes a `Component` argument and uses `GridBagLayout` method `setConstraints` to set the constraints for the `Component`. Method `add` attaches the component to the content pane.

`JButton buttons[ 0 ]` (lines 4849) has `weightx` and `weighty` values of 1. The `fill` variable is `BOTH`. Because `buttons[ 0 ]` is not one of the last two components on the row, it is given a `gridwidth` of 1 and so will occupy one column. The `JButton` is added to the content pane with a call to utility method `addComponent`.

---

[Page 1045]

`JButton buttons[ 1 ]` (lines 5253) has `weightx` and `weighty` values of 1. The `fill` variable is `BOTH`. Line 52 specifies that the `JButton` is to be placed relative to the previous component. The `Button` is added to the `JFrame` with a call to `addComponent`.

`JButton buttons[ 2 ]` (lines 5657) has `weightx` and `weighty` values of 1. The `fill` variable is `BOTH`. This `JButton` is the last component on the line, so `REMAINDER` is used. The `JButton` is added to the content pane with a call to `addComponent`.

---

The `JComboBox` (lines 6062) has a `weightx` of 1 and a `weighty` of 0. The `JComboBox` will not grow in the vertical direction. The `JComboBox` is the only component on the line, so `REMAINDER` is used. The `JComboBox` is added to the content pane with a call to `addComponent`.

`JButton buttons[ 3 ]` (lines 6567) has `weightx` and `weighty` values of 1. The `fill` variable is `BOTH`. This `JButton` is the only component on the line, so `REMAINDER` is used. The `JButton` is added to the content pane with a call to `addComponent`.

`JButton buttons[ 4 ]` (lines 7071) has `weightx` and `weighty` values of 1. The `fill` variable is `BOTH`. This `JButton` is the next-to-last component on the line, so `RELATIVE` is used. The `JButton` is added to the content pane with a call to `addComponent`.

The `JList` (lines 7475) has `weightx` and `weighty` values of 1. The `fill` variable is `BOTH`. The `JList` is added to the content pane with a call to `addComponent`.

## 22.10. Wrap-Up

This chapter completes our introduction to GUI. In this chapter, you learned about more advanced GUI topics, such as menus, sliders, pop-up menus and the multiple-document interface. All these components can be added to existing applications to make them easier to use and understand. In the next chapter, you will learn about multithreading, a powerful capability that allows applications to use threads to perform multiple tasks at once.

## Summary

- `JSliders` enable the user to select from a range of integer values. `JSliders` can display major tick marks, minor tick marks and labels for the tick marks. They also support snap-to ticks, where positioning the thumb between two tick marks causes the thumb to snap to the closest tick mark.
- If a `JSlider` has the focus, the left and right arrow keys cause the thumb of the `JSlider` to decrease or increase by 1. The down and up arrow keys also cause the thumb of the `JSlider` to decrease or increase by 1, respectively. The *PgDn* (page down) *key* and *PgUp* (page up) *key* cause the thumb of the `JSlider` to decrease or increase by block increments of one-tenth of the range of values, respectively. The *Home key* moves the thumb to the minimum value of the `JSlider`, and the *End key* moves it to the maximum value.
- `JSliders` have either horizontal or vertical orientation. For a horizontal `JSlider`, the minimum value is at the extreme left and the maximum value is at the extreme right. For a vertical `JSlider`, the minimum value is at the extreme bottom and the maximum value is at the extreme top. The position of the thumb indicates the current value of the `JSlider`. Method `getValue` of class `JSlider` returns the current thumb position.
- Method `setMajorTickSpacing` of class `JSlider` sets the spacing for tick marks on a `JSlider`. Method `setPaintTicks` with a `TRUE` argument indicates that the tick marks should be displayed.
- `JSliders` generate `ChangeEvent`s when the user interacts with a `JSlider`. A `ChangeListener` declares method `stateChanged` that can respond to `ChangeEvent`s.
- Every window generates window events when the user manipulates it. Interface `WindowListener` provides seven window-event-handling methods `windowActivated`, `windowClosed`, `windowClosing`, `windowDeactivated`, `windowDeiconified`, `windowIconified` and `windowOpened`.
- Menus are an integral part of GUIs. Menus allow the user to perform actions without unnecessarily cluttering a graphical user interface with extra GUI components. In Swing GUIs, menus can be attached only to objects of classes with method `setJMenuBar` (e.g., `JFrame` and `JApplet`).

- The classes used to declare menus are `JMenuBar`, `JMenuItem`, `JMenu`, `JCheckBoxMenuItem` and `JRadioButtonMenuItem`.
- A `JMenuBar` is a container for menus. A `JMenuItem` is a GUI component inside a menu that, when selected, causes an action to be performed. A `JMenu` contains menu items and can be added to a `JMenuBar` or to other `JMenus` as submenus.
- When a menu is clicked, it expands to show its list of menu items. `JMenu` method `addSeparator` adds a separator line to a menu.
- When a `JCheckBoxMenuItem` is selected, a check appears to the left of the menu item. When the `JCheckBoxMenuItem` is selected again, the check is removed.
- When multiple `JRadioButtonMenuItems` are maintained as part of a `ButtonGroup`, only one item in the group can be selected at a given time. When an item is selected, a filled circle appears to its left. When another `JRadioButtonMenuItem` is selected, the filled circle to the left of the previously selected item is removed.
- `AbstractButton` method `setMnemonic` specifies the mnemonic for an `AbstractButton`. Mnemonic characters are normally displayed with an underline.

- A modal dialog box does not allow access to any other window in the application until the dialog is dismissed. The dialogs displayed with class `JOptionPane` are modal dialogs. Class `JDialog` can be used to create your own modal or nonmodal dialogs.
- Context-sensitive pop-up menus are created with class `JPopupMenu`. On most systems, the popup trigger event occurs when the user presses and releases the right mouse button. `MouseEvent` method `isPopupTrigger` returns `TRUE` if the pop-up trigger event occurred.
- `JPopupMenu` method `show` displays a `JPopupMenu`. The first argument specifies the origin component, which helps determine where the `JPopupMenu` will appear. The last two arguments are the coordinates from the origin component's upper-left corner, at which the `JPopupMenu` appears.
- Class `UIManager` contains nested class `LookAndFeelInfo` that maintains information about a look-and-feel.
- `UIManager` static method `getInstalledLookAndFeels` gets an array of `UIManager.LookAndFeelInfo` objects that describe the available look-and-feels.
- `UIManager` static method `setLookAndFeel` changes the look-and-feel. `SwingUtilities` static method `updateComponentTreeUI` changes the look-and-feel of every component attached to its `Component` argument to the new look-and-feel.
- Many of today's applications use a multiple-document interface (MDI) to manage several open documents that are being processed in parallel. Swing's `JDesktopPane` and `JInternalFrame` classes provide support for creating multiple-document interfaces.
- A `JTabbedPane` arranges GUI components into layers in which only one layer is visible at a time. Users access each layer via a tab similar to those on folders in a file cabinet. When the user clicks a tab, the appropriate layer is displayed.
- `BoxLayout` is a layout manager that allows GUI components to be arranged left-to-right or top-to-bottom in a container.
- Class `Box` declares a container with `BoxLayout` as its default layout manager and provides static methods to create a `Box` with a horizontal or vertical `BoxLayout`.
- `GridBagLayout` is a layout manager similar to `GridLayout`. It differs in that each component size can vary, and components can be added in any order.
- A `GridBagConstraints` object specifies how a component is placed in a `GridBagLayout`. Method `setConstraints` of class `GridBagLayout` takes a `Component` argument and a `GridBagConstraints` argument and sets the constraints of the `Component`.

## Self-Review Exercises

22.1 Fill in the blanks in each of the following statements:

- The \_\_\_\_\_ class is used to create a menu object.
- The \_\_\_\_\_ method of class `JMenu` places a separator bar in a menu.
- `JSlider` events are handled by the \_\_\_\_\_ method of interface \_\_\_\_\_.
- The `GridBagConstraints` instance variable \_\_\_\_\_ is set to `CENTER` by default.

22.2 State whether each of the following is *true* or *false*. If *false*, explain why.

- When the programmer creates a `JFrame`, a minimum of one menu must be created and added to the `JFrame`.
- The variable `fill` belongs to the `GridLayout` class.
- Drawing on a GUI component is performed with respect to the (0, 0) upper-left corner coordinate of the component.
- The default layout for a `Box` is `BoxLayout`.

22.3 Find the error(s) in each of the following and explain how to correct the error(s).

- `JMenubar b;`
- `mySlider = JSlider( 1000, 222, 100, 450 );`
- `gbc.fill = GridBagConstraints.NORTHWEST; // set fill`
- ```
// override to paint on a customized Swing component
public void paintcomponent( Graphics g )
{
    g.drawString( "HELLO", 50, 50 );
} // end method paintComponent
```
- ```
// create a JFrame and display it
JFrame f = new JFrame("A Window");
f.setVisible(true);
```

## Answers to Self-Review Exercises

[22.1](#) a) `JMenu`. b) `addSeparator`. c) `stateChanged`, `ChangeListener`. d) `anchor`.

### [22.2](#)

- a. False. A `JFrame` does not require any menus.
- b. False. The variable `fill` belongs to the `GridBagConstraints` class.
- c. True.
- d. True.

### [22.3](#)

- a. `JMenubar` should be `JMenuBar`.
- b. The first argument to the constructor should be either `SwingConstants.HORIZONTAL` or `SwingConstants.VERTICAL`, and the keyword `new` must be used after the `=` operator.
- c. The constant should be either `BOTH`, `HORIZONTAL`, `VERTICAL` or `NONE`.
- d. `paintcomponent` should be `paintComponent`, and the method should call `super.paintComponent( g )` as its first statement.
- e. The `JFrame`'s `setSize` method must also be called to establish the size of the window.

## Exercises

22.4 Fill in the blanks in each of the following statements:

- A `JMenuItem` that is a `JMenu` is called a(n) \_\_\_\_\_.
- Method \_\_\_\_\_ attaches a `JMenuBar` to a `JFrame`.
- Container \_\_\_\_\_ class has a default `BoxLayout`.
- A(n) \_\_\_\_\_ manages a set of child windows declared with class `JInternalFrame`.

22.5 State whether each of the following is *true* or *false*. If *false*, explain why.

- Menus require a `JMenuBar` object so they can be attached to a `JFrame`.
- `BoxLayout` is the default layout manager for a `JFrame`.
- Method `setEditable` is a `JTextComponent` method.
- Class `JFrame` directly extends class `Container`.
- `JApplets` can contain menus.

22.6 Find the error(s) in each of the following. Explain how to correct the error(s).

- ```
x.add( new JMenuItem( "Submenu Color" ) );// create submenu
```
- ```
container.setLayout(m = new GridbagLayout());
```

22.7 Write a program that displays a circle of random size and calculates and displays the area, radius, diameter and circumference. Use the following equations:  $diameter = 2 \times radius$ ,  $area = \pi \times radius^2$ ,  $circumference = 2 \times \pi \times radius$ . Use the constant `Math.PI` for pi ( $\pi$ ). All drawing should be done on a subclass of `JPanel`, and the results of the calculations should be displayed in a read-only `JTextArea`.

22.8 Enhance the program in [Exercise 22.7](#) by allowing the user to alter the radius with a `JSlider`. The program should work for all radii in the range from 100 to 200. As the radius changes, the diameter, area and circumference should be updated and displayed. The initial radius should be 150. Use the equations from [Exercise 22.7](#). All drawing should be done on a subclass of `JPanel`, and the results of the calculations should be displayed in a read-only `JTextArea`.

22.9 Explore the effects of varying the `weightx` and `weighty` values of the program in [Fig. 22.21](#). What happens when a slot has a nonzero weight but is not allowed to fill the whole area (i.e., the `fill` value is not `BOTH`)?

22.10 Write a program that uses the `paintComponent` method to draw the current value of a `JSlider` on a subclass of `JPanel`. In addition, provide a `JTextField` where a specific value can be entered. The `JTextField` should display the current value of the `JSlider` at all times. A `JLabel` should be used to identify the `JTextField`. The `JSlider` methods `setValue` and `getValue` should be used. [Note: The `setValue` method is a `public` method that does not return a value and takes one integer argument, the `JSlider` value, which determines the position of the thumb.]

---

[Page 1051]

- 22.11 Modify the program in [Fig. 22.13](#) by adding a minimum of two new tabs.
- 22.12 Declare a subclass of `JPanel` called `MyColorChooser` that provides three `JSlider` objects and three `JTextField` objects. Each `JSlider` represents the values from 0 to 255 for the red, green and blue parts of a color. Use these values as the arguments to the `Color` constructor to create a new `Color` object. Display the current value of each `JSlider` in the corresponding `JTextField`. When the user changes the value of the `JSlider`, the `JTextField` should be changed accordingly. Use your new GUI component as part of an application that displays the current `Color` value by drawing a filled rectangle.
- 22.13 Modify the `MyColorChooser` class of [Exercise 22.12](#) to allow the user to enter an integer value into a `JTextField` to set the red, green or blue value. When the user presses *Enter* in the `JTextField`, the corresponding `JSlider` should be set to the appropriate value.
- 22.14 Modify the application in [Exercise 22.13](#) to draw the current color as a rectangle on an instance of a subclass of `JPanel` which provides its own `paintComponent` method to draw the rectangle and provides `set` methods to set the red, green and blue values for the current color. When any `set` method is invoked, the drawing panel should automatically `repaint` itself.
- 22.15 Modify the application in [Exercise 22.14](#) to allow the user to drag the mouse across the drawing panel (a subclass of `JPanel`) to draw a shape in the current color. Enable the user to choose what shape to draw.
- 22.16 Modify the application in [Exercise 22.15](#) to provide the user with the ability to terminate the application by clicking the close box on the window that is displayed and by selecting `Exit` from a File menu. Use the techniques shown in [Fig. 22.5](#).
- 22.17 (*Complete Drawing Application*) Using the techniques developed in this chapter and [Chapter 11](#), create a complete drawing application. The program should use the GUI components from [Chapter 11](#) and [Chapter 22](#) to enable the user to select the shape, color and fill characteristics. Each shape should be stored in an array of `MyShape` objects, where `MyShape` is the superclass in your hierarchy of shape classes. Use a `JDesktopPane` and `JInternalFrame`s to allow the user to create multiple separate drawings in separate child windows. Create the user interface as a separate child window containing all the GUI components that allow the user to determine the characteristics of the shape to be drawn. The user can then click in any `JInternalFrame` to draw the shape.

## OBJECTIVES

In this chapter you will learn:

- What threads are and why they are useful.
- How threads enable you to manage concurrent activities.
- The life cycle of a thread.
- Thread priorities and scheduling.
- To create and execute `Runnable`s.
- Thread synchronization.
- What producer/consumer relationships are and how they are implemented with multithreading.
- To display output from multiple threads in a Swing GUI.
- About `Callable` and `Future`.

## 23.1. Introduction

It would be nice if we could perform one action at a time and perform it well, but that is usually difficult to do. The human body performs a great variety of operations [in parallel](#), as we will say throughout this chapter, [concurrently](#). Respiration, blood circulation, digestion, thinking and walking, for example, can occur concurrently. All the senses—sight, touch, smell, taste and hearing—can be employed at once. Computers, too, can perform operations concurrently. It is common for personal computers to compile a program, send a file to a printer and receive electronic mail messages over a network concurrently. Only computers that have multiple processors can truly execute operations concurrently. Operating systems on single-processor computers use various techniques to simulate concurrency, but on such computers only a single operation can execute at once.

Most programming languages do not enable programmers to specify concurrent activities. Rather, the languages generally provide control statements that only enable programmers to perform one action at a time, proceeding to the next action after the previous one has finished. Historically, concurrency has been implemented with operating system primitives available only to experienced systems programmers.

The Ada programming language, developed by the United States Department of Defense, made concurrency primitives widely available to defense contractors building military command-and-control systems. However, Ada has not been widely used in academia and commercial industry.

Java makes concurrency available to the applications programmer through its APIs. The programmer specifies that applications contain [threads of execution](#), where each thread designates a portion of a program that may execute concurrently with other threads. This capability, called [multithreading](#), gives the Java programmer powerful capabilities not available in the core C and C++ languages on which Java is based.

### Performance Tip 23.1

*A problem with single-threaded applications is that lengthy activities must complete before other activities can begin. In a multithreaded application, threads can be distributed across multiple processors (if they are available) so that multiple tasks are performed concurrently and the application can operate more efficiently. Multithreading can also increase performance on single-processor systems that simulate concurrency when one thread cannot proceed, another can use the processor.*

### Portability Tip 23.1

*Unlike languages that do not have built-in multithreading capabilities (such as C and C++) and must therefore make nonportable calls to operating system multithreading primitives, Java includes multithreading primitives as part of the language itself and as part of its libraries. This facilitates manipulating threads in a portable manner across platforms.*

We will discuss many applications of [concurrent programming](#). For example, when programs download large files, such as audio clips or video clips, over the Internet, users may not want to wait until an entire lengthy clip downloads before starting the playback. To solve this problem, we can put multiple threads to work: one thread downloads the clip, and another plays it. These activities proceed concurrently. To avoid choppy playback, we [synchronize](#) the threads so that the player thread does not begin until there is a sufficient amount of the clip in memory to keep the player thread busy.

Another example of multithreading is Java's [garbage collection](#). C and C++ require the programmer to reclaim dynamically allocated memory explicitly. Java provides a [garbage-collector thread](#) that reclaims memory which is no longer needed.

Writing multithreaded programs can be tricky. Although the human mind can perform functions concurrently, people find it difficult to jump between parallel trains of thought. To see why multithreading can be difficult to program and understand, try the following experiment: Open three books to page 1, and try reading the books concurrently. Read a few words from the first book, then read a few words from the second book, then read a few words from the third book, then loop back and read the next few words from the first book, and so on. After this experiment, you will appreciate the challenges of multithreading: switching between books, reading briefly, remembering your place in each book, moving the book you are reading closer so you can see it and pushing books you are not reading aside, and, amid all this chaos, trying to comprehend the content of the books!

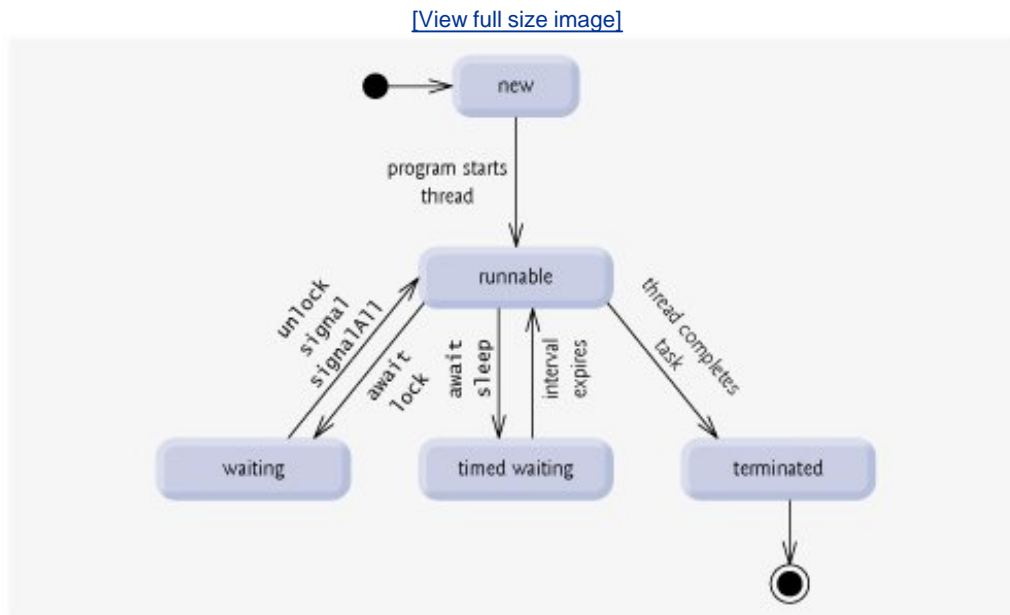

Programming concurrent applications is a difficult and error-prone undertaking. Even some of the simplest concurrent applications are beyond the capability of beginner programmers. If you find that you must use synchronization in a program, you should follow some simple guidelines. First, use existing classes from the Java API (such as the [ArrayBlockingQueue](#) class discussed in [Section 23.9](#), Producer/Consumer Relationship: [ArrayBlockingQueue](#)) that manage synchronization for you. The classes in the Java API have been fully tested and debugged and help you avoid common traps and pitfalls. Second, if you find that you need more custom functionality than that provided in the Java APIs, you should use the [synchronized](#) keyword and [Object](#) methods [wait](#), [notify](#) and [notifyAll](#) (discussed in [Section 23.12](#), Monitors and Monitor Locks). Finally, if you need even more complex capabilities, then you should use the [Lock](#) and [Condition](#) interfaces that are introduced in [Section 23.5](#), Thread Synchronization).

The [Lock](#) and [Condition](#) interfaces are advanced tools and should be used only by advanced programmers who are familiar with the common traps and pitfalls of concurrent programming with synchronization. We explain these topics in this chapter for a number of reasons. For one, they provide a solid basis for understanding how concurrent applications synchronize access to shared memory. Even, if an application does not use these tools explicitly, the concepts are still important to understand. We have also discussed these topics to highlight the new concurrency features introduced by J2SE 5.0. Finally, by showing you the complexity involved in using these low-level features, we hope to impress upon you the importance of using prepackaged concurrent capabilities whenever possible.

## 23.2. Thread States: Life Cycle of a Thread

At any time, a thread is said to be in one of several [thread states](#) that are illustrated in the UML state diagram in [Fig. 23.1](#). A few of the terms in the diagram are defined in later sections.

Figure 23.1. Thread life-cycle UML state diagram.

A new thread begins its life cycle in the [new](#) state. It remains in this state until the program starts the thread, which places the thread in the [runnable](#) state. A thread in this state is considered to be executing its task.

Sometimes a thread transitions to the [waiting](#) state while the thread waits for another thread to perform a task. Once in this state, a thread transitions back to the [runnable](#) state only when another thread signals the waiting thread to continue executing.

A [runnable](#) thread can enter the [timed waiting](#) state for a specified interval of time. A thread in this state transitions back to the [runnable](#) state when that time interval expires or when the event it is waiting for occurs. *Timed waiting* threads cannot use a processor, even if one is available. A thread can transition to the *timed waiting* state if it provides an optional wait interval when it is waiting for another thread to perform a task. Such a thread will return to the [runnable](#) state when it is signaled by another thread or when the timed interval expires whichever comes first. Another way to place a thread in the *timed waiting* state is to put the thread to sleep. A [sleeping thread](#) remains in the *timed waiting* state for a designated period of time (called a [sleep interval](#)) at which point it returns to the [runnable](#) state. Threads sleep when they momentarily do not have work to perform. For example, a word processor may contain a thread that periodically writes a copy of the current document to disk for recovery purposes. If the thread did not sleep between successive backups, it would require a loop in which it continually tests whether it should write a copy of the document to disk. This loop would consume processor time without performing productive work, thus reducing system performance. In this case, it is more efficient for the thread to specify a sleep interval (equal to the period between successive backups) and enter the *timed waiting* state. This thread is returned to the [runnable](#) state when its sleep interval expires, at which point it writes a copy of the document to disk and reenters the *timed waiting* state.

A *runnable* thread enters the *terminated* state when it completes its task or otherwise terminates (perhaps due to an error condition). In the UML state diagram in [Fig. 23.1](#), the *terminated* state is followed by the UML final state (the bull's-eye symbol) to indicate the end of the state transitions.

At the operating-system level, Java's *runnable* state actually encompasses two separate states ([Fig. 23.2](#)). The operating system hides these two states from the Java Virtual Machine (JVM), which only sees the *runnable* state. When a thread first transitions to the *runnable* state from the *new* state, the thread is in the *ready* state. A *ready* thread enters the *running* state (i.e., begins executing) when the operating system assigns the thread to a processor also known as *dispatching the thread*. In most operating systems, each thread is given a small amount of processor time called a *quantum* or *timeslice* with which to perform its task. When the thread's quantum expires, the thread returns to the *ready* state and the operating system assigns another thread to the processor (see [Section 23.3](#)). Transitions between these states are handled solely by the operating system. The JVM does not "see" these two states; it simply views a thread as being in the *runnable* state and leaves it up to the operating system to transition threads between the *ready* and *running* states. The process that an operating system uses to decide which thread to dispatch is known as *thread scheduling* and is dependent on thread priorities (discussed in the next section).

Figure 23.2. Operating system's internal view of Java's runnable state.

[\[View full size image\]](#)

## 23.3. Thread Priorities and Thread Scheduling

Every Java thread has a [priority](#) that helps the operating system determine the order in which threads are scheduled. Java priorities are in the range between [MIN\\_PRIORITY](#) (a constant of 1) and [MAX\\_PRIORITY](#) (a constant of 10). Informally, threads with higher priority are more important to a program and should be allocated processor time before lower-priority threads. However, thread priorities cannot guarantee the order in which threads execute. By default, every thread is given priority [NORM\\_PRIORITY](#) (a constant of 5). Each new thread inherits the priority of the thread that created it.

---

[Page 1057]

[*Note:* These constants ([MAX\\_PRIORITY](#), [MIN\\_PRIORITY](#) and [NORM\\_PRIORITY](#)) are declared in the [Thread](#) class. It is recommended that you do not explicitly create and use [Thread](#) objects to implement concurrency, but rather use the [Runnable](#) interface (which is described in [Section 23.4](#)). The [Thread](#) class does contain some [static](#) methods that are useful, as you will see later in this chapter.]

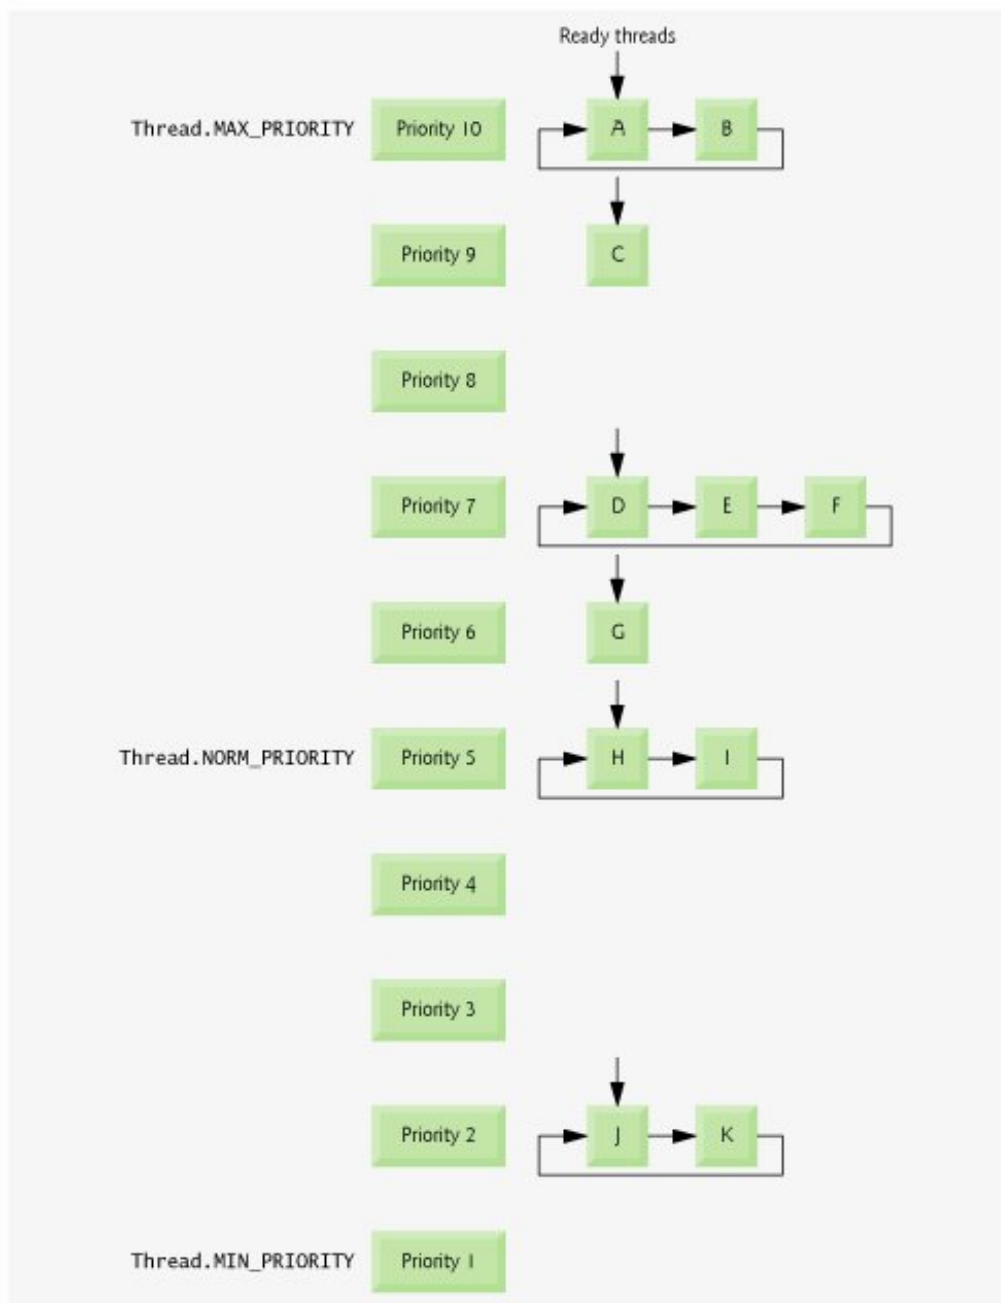

Most Java platforms support timeslicing, which enables threads of equal priority to share a processor. Without timeslicing, each thread in a set of equal-priority threads runs to completion (unless it leaves the *runnable* state and enters the *waiting* or *timed waiting* state, or gets interrupted by a higher-priority thread) before other threads of equal priority get a chance to execute. With timeslicing, even if the thread has not finished executing when the quantum expires, the processor is taken away from that thread and given to the next thread of equal priority, if one is available.

The job of an operating system's [thread scheduler](#) is to determine which thread runs next. One simple implementation of the thread scheduler keeps the highest-priority thread *running* at all times and, if there is more than one highest-priority thread, ensures that all such threads execute for a quantum each in [round-robin](#) fashion. [Figure 23.3](#) illustrates a multi-level priority queue for threads. In the figure, assuming a single-processor computer, threads *A* and *B* each execute for a quantum in round-robin fashion until both threads complete execution. This means that *A* gets a quantum of time to run. Then *B* gets a quantum. Then *A* gets another quantum. Then *B* gets another quantum. This continues until one thread completes. The processor then devotes all its power to the thread that remains (unless another thread of that priority becomes ready). Next, thread *C* runs to completion (assuming that no higher-priority threads arrive). Threads *D*, *E* and *F* each execute for a quantum in round-robin fashion until they all complete execution (again assuming that no higher-priority threads arrive). This process continues until all threads run to completion.

Figure 23.3. Thread-priority scheduling.

(This item is displayed on page 1058 in the print version)

[\[View full size image\]](#)

## Portability Tip 23.2

*Thread scheduling is platform dependent and an application that uses multithreading could behave differently on separate Java implementations.*

When a higher-priority thread enters the *ready* state, the operating system generally preempts the currently *running* thread (an operation known as [preemptive scheduling](#)). Depending on the operating system, higher-priority threads could postpone possibly indefinitely the execution of lower-priority threads. Such [indefinite postponement](#) often is referred to more colorfully as [starvation](#).

## Portability Tip 23.3

*When designing applets and applications that use threads, you must consider the threading capabilities of all the platforms on which the applets and applications will execute.*

J2SE 5.0 provides higher-level concurrency utilities to hide some complexity and make multithreaded programs less error prone (though they are still certainly complex). Thread priorities are still used behind the scenes to interact with the operating system, but most programmers who use J2SE 5.0 multithreading will not be concerned with setting and adjusting thread priorities. You can learn more about priorities and threading at [java.sun.com/j2se/5.0/docs/api/java/lang/Thread.html](http://java.sun.com/j2se/5.0/docs/api/java/lang/Thread.html).

[< PREVIOUS](#)[NEXT >](#)

## 23.4. Creating and Executing Threads

In J2SE 5.0, the preferred means of creating a multithreaded application is to implement the `Runnable` interface (package `java.lang`) and use built-in methods and classes to create `Threads` that execute the `Runnables`. The `Runnable` interface declares a single method named `run`. `Runnables` are executed by an object of a class that implements the `Executor` interface (package `java.util.concurrent`). This interface declares a single method named `execute`. An `Executor` object typically creates and manages a group of threads called a `thread pool`. These threads execute the `Runnable` objects passed to the `execute` method. The `Executor` assigns each `Runnable` to one of the available threads in the thread pool. If there are no available threads in the thread pool, the `Executor` creates a new thread or waits for a thread to become available and assigns that thread the `Runnable` that was passed to method `execute`. Depending on the `Executor` type, there may be a limit to the number of threads that can be created. Interface `ExecutorService` (package `java.util.concurrent`) is a subinterface of `Executor` that declares a number of other methods for managing the life cycle of the `Executor`. An object that implements the `ExecutorService` interface can be created using `static` methods declared in class `Executors` (package `java.util.concurrent`). We use these interfaces and methods in the next application, which executes three threads.

Class `PrintTask` (Fig. 23.4) implements `Runnable` (line 5), so that each `PrintTask` object can execute concurrently. Variable `sleepTime` (line 7) stores a random integer value (line 17) chosen when the `PrintTask` constructor executes. Each thread running a `PrintTask` object sleeps for the amount of time specified by the corresponding `PrintTask` object's `sleepTime`, then outputs its name.

Figure 23.4. Threads sleeping and awakening.

(This item is displayed on page 1060 in the print version)

```
1 // Fig. 23.4: PrintTask.java
2 // PrintTask class sleeps for a random time from 0 to 5 seconds
3 import java.util.Random;
4
5 class PrintTask implements Runnable
6 {
7 private int sleepTime; // random sleep time for thread
8 private String threadName; // name of thread
9 private static Random generator = new Random();
10
11 // assign name to thread
12 public PrintTask(String name)
13 {
14 threadName = name; // set name of thread
15
16 // pick random sleep time between 0 and 5 seconds
17 sleepTime = generator.nextInt(5000);
18 } // end PrintTask constructor
19
20 // method run is the code to be executed by new thread
21 public void run()
22 {
```

```

23 try // put thread to sleep for sleepTime amount of time
24 {
25 System.out.printf("%s going to sleep for %d milliseconds.\n",
26 threadName, sleepTime);
27
28 Thread.sleep(sleepTime); // put thread to sleep
29 } // end try
30 // if thread interrupted while sleeping, print stack trace
31 catch (InterruptedException exception)
32 {
33 exception.printStackTrace();
34 } // end catch
35
36 // print thread name
37 System.out.printf("%s done sleeping\n", threadName);
38 } // end method run
39 } // end class PrintTask

```

When a `PrintTask` is assigned to a processor for the first time, its `run` method (lines 21-38) begins execution. Lines 25-26 display a message indicating the name of the currently executing thread and stating that the thread is going to sleep for a certain number of milliseconds. Line 26 uses the `threadName` field which was initialized at line 14 with the `PrintTask` constructor's argument. Line 28 invokes `static` method `sleep` of class `Thread` to place the thread into the *timed waiting* state. At this point, the thread loses the processor, and the system allows another thread to execute. When the thread awakens, it reenters the *runnable* state. When the `PrintTask` is assigned to a processor again, line 37 outputs the thread's name in a message that indicates the thread is done sleeping then method `run` terminates. Note that the `catch` at lines 31-34 is required because method `sleep` might throw an `InterruptedException`, which is a checked exception. Such an exception occurs if a sleeping thread's `interrupt` method is called. Most programmers do not directly manipulate `Thread` objects, so `InterruptedExceptions` are unlikely to occur.

[Figure 23.5](#) creates three threads of execution using the `PrintTask` class. Method `main` (lines 8-28) creates and names three `PrintTask` objects (lines 11-13). Line 18 creates a new `ExecutorService`. This line uses the `newFixedThreadPool` method of class `Executors`, which creates a pool consisting of a fixed number of `Threads` as indicated by the method's argument (in this case, 3). These `Threads` are used by `threadExecutor` to execute the `Runnable`s. If method `execute` is called and all the threads in the `ExecutorService` are being used, the `Runnable` will be placed in a queue and assigned to the first thread that completes its previous task. `Executors` method `newCachedThreadPool` returns an `ExecutorService` that creates new threads as they are needed by the application.

Figure 23.5. Creates three `PrintTasks` and executes them.

(This item is displayed on page 1061 in the print version)

```

1 // Fig. 23.5: RunnableTester.java
2 // Multiple threads printing at different intervals.
3 import java.util.concurrent.Executors;
4 import java.util.concurrent.ExecutorService;
5
6 public class RunnableTester
7 {
8 public static void main(String[] args)
9 {
10 // create and name each runnable
11 PrintTask task1 = new PrintTask("thread1");
12 PrintTask task2 = new PrintTask("thread2");
13 PrintTask task3 = new PrintTask("thread3");

```

```

14
15 System.out.println("Starting threads");
16
17 // create ExecutorService to manage threads
18 ExecutorService threadExecutor = Executors.newFixedThreadPool(3);
19
20 // start threads and place in runnable state
21 threadExecutor.execute(task1); // start task1
22 threadExecutor.execute(task2); // start task2
23 threadExecutor.execute(task3); // start task3

Lines 21-23 invoke the `ExecutorService`'s `execute` method. This method creates a new `Thread` inside the `ExecutorService` to run the `Runnable` passed to it as an argument (in this case a `PrintTask`) and transitions that `Thread` from the *new* state to the *runnable* state. Method `execute` returns immediately from each invocation; the program does not wait for each `PrintTask` to finish. Line 25 calls `ExecutorService` method `shutdown`, which will end each `Thread` in `threadExecutor` as soon as each finishes executing its `Runnable`. Line 27 outputs a message indicating that the threads were started. [Note: Line 18 creates the `ExecutorService` using method `newFixedThreadPool` and the argument 3. This program executes only three `Runnables`, so a new `Thread` will be created by the `ExecutorService` for each `Runnable`. If the program executed more than three `Runnables`, additional `Threads` would not be created, but rather an existing `Thread`

would be reused when it completed the `Runnable` assigned to it.]

---

[Page 1060]

The code in method `main` executes in the `main thread`. This thread is created by the JVM and executes the `main` method. The code in the `run` method of `PrintTask` (lines 2138 of [Fig. 23.4](#)) executes in the threads created by the `ExecutorService`. When method `main` terminates (line 28), the program itself continues running because there are still threads that are alive (i.e., the threads started by `ThreadPoolExecutor` that have not yet reached the *terminated* state). The program will not terminate until its last thread completes execution.

---

[Page 1061]

---

[Page 1062]

The sample outputs for this program show each thread's name and sleep time as the thread goes to sleep. The thread with the shortest sleep time normally awakens first, indicates that it is done sleeping and terminates. In [Section 23.8](#), we discuss multithreading issues that could prevent the thread with the shortest sleep time from awakening first. In the first output, the main thread terminates before any of the other threads output their names and sleep times. This shows that the main thread runs to completion before any of the other threads get a chance to run. In the second output, the first two threads output their names and sleep times before the main thread terminates. This shows that the operating system allowed other threads to execute before the main thread terminated. This is an example of the round-robin scheduling we discussed in [Section 23.3](#).

## 23.5. Thread Synchronization

Often, multiple threads of execution manipulate a shared object in memory. When multiple threads share an object and that object is modified by one or more of the threads, indeterminate results may occur (as we will soon see in the chapter examples) unless the shared object is managed properly. If one thread is in the process of updating a shared object and another thread tries to update it too, it is possible that part of the object will reflect the information from one thread while another part of the object reflects information from a different thread. When this happens, the program's behavior cannot be trusted. Sometimes the program will produce the correct results, but other times it will produce incorrect results. In either case there will be no error message to indicate that the shared object was manipulated incorrectly.

The problem can be solved by giving one thread at a time exclusive access to code that manipulates the shared object. During that time, other threads desiring to manipulate the object are kept waiting. When the thread with exclusive access to the object finishes manipulating it, one of the threads that was kept waiting is allowed to proceed. In this fashion, each thread accessing the shared object excludes all other threads from doing so simultaneously. This is called **mutual exclusion**. Mutual exclusion allows the programmer to perform **thread synchronization**, which coordinates access to shared data by multiple concurrent threads.

Java uses **locks** to perform synchronization. Any object can contain an object that implements the **Lock** interface (package `java.util.concurrent.locks`). A thread calls the **Lock**'s **lock** method to **obtain the lock**. Once a **Lock** has been obtained by one thread, the **Lock** object will not allow another thread to obtain the lock until the first thread releases the **Lock** (by calling the **Lock**'s **unlock** method). If there are several threads trying to call method **lock** on the same **Lock** object at the same time, only one thread may obtain the lock at a time all other threads attempting to obtain the **Lock** contained in the same object are placed in the *waiting* state for that lock. When a thread calls method **unlock**, the lock on the object is released and the highest-priority waiting thread attempting to lock the object proceeds. Class **ReentrantLock** (package `java.util.concurrent.locks`) is a basic implementation of the **Lock** interface. The constructor for a **ReentrantLock** takes a **boolean** argument that specifies whether the lock has a **fairness policy**. If this is set to **true**, the **ReentrantLock**'s fairness policy states that the longest-waiting thread will acquire the lock when it is available. If this is set to **false**, there is no guarantee as to which waiting thread will acquire the lock when it is available.

### Performance Tip 23.2

*Using a Lock with a fairness policy helps avoid indefinite postponement, but can also dramatically reduce the overall efficiency of a program. Because of the large decrease in performance, fair locks are only necessary in extreme circumstances.*

If a thread that owns the lock on an object determines that it cannot continue with its task until some condition is satisfied, the thread can wait on a **condition variable**. This removes the thread from contention for the processor, places it in a wait queue for the condition variable and releases the lock on the object. Condition variables must be associated with a **Lock** and are created by calling **Lock** method **newCondition**, which returns an object that implements the **Condition** interface (package `java.util.concurrent.locks`). To wait on a condition variable, the thread can call the **Condition**'s **await** method. This immediately releases the associated **Lock** and places the thread in the *waiting* state for that **Condition**. Other threads can then try to obtain the **Lock**. When a *runnable* thread completes a task and

determines that the *waiting* thread can now continue, the *runnable* thread can call `Condition` method `signal` to allow a thread in that `Condition`'s *waiting* state to return to the *runnable* state. At this point, the thread that transitioned from the *waiting* state to the *runnable* state can attempt to reacquire the `Lock` on the object. Even if it is able to reacquire the `Lock`, the thread still might not be able to perform its task at this time in which case the thread can call method `await` to release the `Lock` and reenter the *waiting* state. If multiple threads are in a `Condition`'s *waiting* state when `signal` is called, the default implementation of `Condition` signals the longest-waiting thread to move to the *runnable* state. If a thread calls `Condition` method `signalAll`, then all the threads waiting for that condition move to the *runnable* state and become eligible to reacquire the `Lock`. Only one of those threads can obtain the `Lock` on the object at a time; other threads that attempt to acquire the same `Lock` will wait until the `Lock` becomes available again. If the `Lock` was created with a fairness policy, the longest-waiting thread will then acquire the `Lock`. When a thread is finished with a shared object, it must call method `unlock` to release the `Lock`.

## Common Programming Error 23.1

*Deadlock occurs when a waiting thread (let us call this thread1) cannot proceed because it is waiting (either directly or indirectly) for another thread (let us call this thread2) to proceed, while simultaneously thread2 cannot proceed because it is waiting (either directly or indirectly) for thread1 to proceed. Two threads are waiting for each other, so the actions that would enable each thread to continue execution never occur.*

## Error-Prevention Tip 23.1

*When multiple threads manipulate a shared object using locks, ensure that if one thread calls method `await` to enter the waiting state for a condition variable, a separate thread eventually will call `Condition` method `signal` to transition the thread waiting on the condition variable back to the runnable state. If multiple threads may be waiting on the condition variable, a separate thread can call `Condition` method `signalAll` as a safeguard to ensure that all the waiting threads have another opportunity to perform their tasks. If this is not done, indefinite postponement or deadlock could occur.*

## Software Engineering Observation 23.1

*The locking that occurs with the execution of the `lock` and `unlock` methods could lead to deadlock if the locks are never released. Calls to method `unlock` should be placed in `finally` blocks to ensure that locks are released and avoid these kinds of deadlocks.*

## Performance Tip 23.3

*Synchronization to achieve correctness in multithreaded programs can make programs run more slowly, as a result of thread overhead and the frequent transition of threads between the waiting and runnable states. There is not much to say, however, for highly efficient yet incorrect multithreaded programs!*

## Common Programming Error 23.2

*It is an error if a thread issues an `await`, a `signal`, or a `signalAll` on a condition variable without having acquired the lock for that condition variable. This causes an `IllegalMonitorStateException`.*

[< PREV](#)[NEXT >](#)

## 23.6. Producer/Consumer Relationship without Synchronization

In a [producer/consumer relationship](#), the [producer](#) portion of an application generates data and stores it in a shared object, and the [consumer](#) portion of an application reads data from the shared object. One example of a common producer/consumer relationship is print spooling. A word processor spools data to a buffer (typically a file) and that data is subsequently consumed by the printer as it prints the document. Similarly, an application that copies data onto compact discs places data in a fixed-size buffer that is emptied as the CD-RW drive burns the data onto the compact disc.

In a multithreaded producer/consumer relationship, a [producer thread](#) generates data and places it in a shared object called a [buffer](#). A [consumer thread](#) reads data from the buffer. If the producer waiting to put the next data into the buffer determines that the consumer has not yet read the previous data from the buffer, the producer thread should call [await](#) so that the consumer can read the data before further updates; otherwise the consumer never sees the previous data and that data is lost to the application. When the consumer thread reads the data, it should call [signal](#) to allow a waiting producer to store the next value. If a consumer thread finds the buffer empty or finds that the previous data has already been read, the consumer should call [await](#); otherwise the consumer might read old data again from the buffer. When the producer places the next data into the buffer, the producer should call [signal](#) to allow the consumer thread to proceed, so that the consumer can read the new data.

Let us consider how logic errors can arise if we do not synchronize access among multiple threads manipulating shared data. Our next example ([Fig. 23.6](#)[Fig. 23.10](#)) implements a producer/consumer relationship in which a producer thread writes the numbers 1 through 10 into a shared buffer a memory location shared between two threads (a single `int` variable called `buffer` in line 6 of [Fig. 23.9](#) in this example). The consumer thread reads this data from the shared buffer and displays the data. The program's output shows the values that the producer writes (produces) into the shared buffer and the values that the consumer reads (consumes) from the shared buffer.

Figure 23.6. **Buffer** interface used in producer/consumer examples.

(This item is displayed on page 1065 in the print version)

```
1 // Fig. 23.6: Buffer.java
2 // Buffer interface specifies methods called by Producer and Consumer.
3
4 public interface Buffer
5 {
6 public void set(int value); // place int value into Buffer
7 public int get(); // return int value from Buffer
8 } // end interface Buffer
```

Each value the producer thread writes to the shared buffer must be consumed exactly once by the consumer thread. However, the threads in this example are not synchronized. Therefore, data can be lost if the producer places new data into the shared buffer before the consumer consumes the previous data. Also, data can be incorrectly duplicated if the consumer consumes data again before the producer produces the next value. To show these possibilities, the consumer thread in the following example keeps a total of all the values it reads. The producer thread produces values from 1 through 10. If the consumer reads each value produced once and only once, the total will be 55. However, if you execute this program several times, you

will see that the total is not always 55 (as shown in the outputs in [Fig. 23.10](#)). To emphasize the point, the producer and consumer threads in the example each sleep for random intervals of up to three seconds between performing their tasks. Thus, we do not know exactly when the producer thread will attempt to write a new value, nor do we know when the consumer thread will attempt to read a value.

---

[Page 1065]

The program consists of interface `Buffer` ([Fig. 23.6](#)) and four classes `Producer` ([Fig. 23.7](#)), `Consumer` ([Fig. 23.8](#)), `UnsynchronizedBuffer` ([Fig. 23.9](#)) and `SharedBufferTest` ([Fig. 23.10](#)). Interface `Buffer` declares methods `set` and `get` that a `Buffer` must implement to enable the `Producer` thread to place a value in the `Buffer` and the `Consumer` thread to retrieve a value from the `Buffer`. We will see the implementation of this interface in [Fig. 23.9](#).

Figure 23.7. `Producer` represents the producer thread in a producer/consumer relationship.

(This item is displayed on page 1066 in the print version)

```
1 // Fig. 23.7: Producer.java
2 // Producer's run method stores the values 1 to 10 in buffer.
3 import java.util.Random;
4
5 public class Producer implements Runnable
6 {
7 private static Random generator = new Random();
8 private Buffer sharedLocation; // reference to shared object
9
10 // constructor
11 public Producer(Buffer shared)
12 {
13 sharedLocation = shared;
14 } // end Producer constructor
15
16 // store values from 1 to 10 in sharedLocation
17 public void run()
18 {
19 int sum = 0;
20
21 for (int count = 1; count <= 10; count++)
22 {
23 try // sleep 0 to 3 seconds, then place value in Buffer
24 {
25 Thread.sleep(generator.nextInt(3000)); // sleep thread
26 sharedLocation.set(count); // set value in buffer
27 sum += count; // increment sum of values
28 System.out.printf("\t%2d\n", sum);
29 } // end try
30 // if sleeping thread interrupted, print stack trace
31 catch (InterruptedException exception)
32 {
33 exception.printStackTrace();
34 } // end catch
35 } // end for
36
37 System.out.printf("\n%s\n%s\n", "Producer done producing.",
38 "Terminating Producer.");
39 } // end method run
```

```
40 } // end class Producer
```

Figure 23.8. **Consumer** represents the consumer thread in a producer/consumer relationship.

(This item is displayed on page 1067 in the print version)

```
1 // Fig. 23.8: Consumer.java
2 // Consumer's run method loops ten times reading a value from buffer.
3 import java.util.Random;
4
5 public class Consumer implements Runnable
6 {
7 private static Random generator = new Random();
8 private Buffer sharedLocation; // reference to shared object
9
10 // constructor
11 public Consumer(Buffer shared)
12 {
13 sharedLocation = shared;
14 } // end Consumer constructor
15
16 // read sharedLocation's value four times and sum the values
17 public void run()
18 {
19 int sum = 0;
20
21 for (int count = 1; count <= 10; count++)
22 {
23 // sleep 0 to 3 seconds, read value from buffer and add to sum
24 try
25 {
26 Thread.sleep(generator.nextInt(3000));
27 sum += sharedLocation.get();
28 System.out.printf("\t\t\t%2d\n", sum);
29 } // end try
30 // if sleeping thread interrupted, print stack trace
31 catch (InterruptedException exception)
32 {
33 exception.printStackTrace();
34 } // end catch
35 } // end for
36
37 System.out.printf("\n%s %d.\n%s\n",
38 "Consumer read values totaling", sum, "Terminating Consumer.");
39 } // end method run
40 } // end class Consumer
```

Figure 23.9. **UnsynchronizedBuffer** maintains the shared integer that is accessed by a producer thread and a consumer thread via methods **set** and **get**.

(This item is displayed on page 1068 in the print version)

```

1 // Fig. 23.9: UnsynchronizedBuffer.java
2 // UnsynchronizedBuffer represents a single shared integer.
3
4 public class UnsynchronizedBuffer implements Buffer
5 {
6 private int buffer = -1; // shared by producer and consumer threads
7
8 // place value into buffer
9 public void set(int value)
10 {
11 System.out.printf("Producer writes\t%2d", value);
12 buffer = value;
13 } // end method set
14
15 // return value from buffer
16 public int get()
17 {
18 System.out.printf("Consumer reads\t%2d", buffer);
19 return buffer;
20 } // end method get
21 } // end class UnsynchronizedBuffer

```

Figure 23.10. **SharedBufferTest** sets up a producer/consumer application that uses an unsynchronized buffer.

(This item is displayed on pages 1069 - 1071 in the print version)

```

1 // Fig 23.10: SharedBufferTest.java
2 // Application shows two threads manipulating an unsynchronized buffer.
3 import java.util.concurrent.ExecutorService;
4 import java.util.concurrent.Executors;
5
6 public class SharedBufferTest
7 {
8 public static void main(String[] args)
9 {
10 // create new thread pool with two threads
11 ExecutorService application = Executors.newFixedThreadPool(2);
12
13 // create UnsynchronizedBuffer to store ints
14 Buffer sharedLocation = new UnsynchronizedBuffer();
15
16 System.out.println("Action\t\tValue\tProduced\tConsumed");
17 System.out.println("-----\t\t\t-----\t\t\t-----\n");
18
19 // try to start producer and consumer giving each of them access
20 // to sharedLocation
21 try
22 {
23 application.execute(new Producer(sharedLocation));
24 application.execute(new Consumer(sharedLocation));
25 } // end try
26 catch (Exception exception)
27 {
28 exception.printStackTrace();

```

```
29 } // end catch
30
31 application.shutdown(); // terminate application when threads end
32 } // end main
33 } // end class SharedBufferTest
```

| Action                            | Value | Produced | Consumed |
|-----------------------------------|-------|----------|----------|

```
Consumer read values totaling 19.
Terminating Consumer.
Producer writes 7 28
Producer writes 8 36
Producer writes 9 45
Producer writes 10 55
Producer done producing.
Terminating Producer.
```

Class `Producer` ([Fig. 23.7](#)) implements the `Runnable` interface, allowing it to be executed in a separate thread. The constructor (lines 1114) initializes `Buffer` reference `sharedLocation` with an object created in `main` (line 14 of [Fig. 23.10](#)) and passed to the constructor in the parameter `shared`. As we will see, this is an `UnsynchronizedBuffer` object that implements interface `Buffer` without synchronizing access to the shared object. The `Producer` `Thread` in this program executes the tasks specified in method `run` (lines 1739). Each iteration of the loop (lines 2135) invokes `Thread` method `sleep` (line 25) to place the `Producer` `Thread` into the *timed waiting* state for a random time interval between 0 and 3 seconds. When the thread awakens, line 26 passes the value of control variable `count` to the `Buffer` object's `set` method to set the shared buffer's value. Line 27 keeps a total of all the values produced so far and line 28 outputs that value. When the loop completes, lines 3738 display a message indicating that the thread has finished producing data and is terminating. Next, method `run` terminates which indicates that the `Producer` completed its task. It is important to note that any method called from a thread's `run` method (e.g., `Buffer` method `set`) executes as part of that thread of execution. In fact, each thread has its own method call stack. This fact becomes important in [Section 23.7](#) when we add synchronization to the producer/consumer relationship.

Class `Consumer` ([Fig. 23.8](#)) also implements interface `Runnable`, allowing the `Consumer` to be executed concurrently with the `Producer`. The constructor (lines 1114) initializes `Buffer` reference `sharedLocation` with an object that implements the `Buffer` interface created in `main` ([Fig. 23.10](#)) and passed to the constructor as the parameter `shared`. As we will see, this is the same `UnsynchronizedBuffer` object that is used to initialize the `Producer` object; thus, the two threads share the same object. The `Consumer` thread in this program performs the tasks specified in method `run` (lines 1739). The loop at lines 2135 loops ten times. Each iteration of the loop invokes `Thread` method `sleep` (line 26) to put the `Consumer` thread into the *timed waiting* state for between 0 and 3 seconds. Next, line 27 uses the `Buffer`'s `get` method to retrieve the value in the shared buffer, then adds the value to variable `sum`. Line 28 displays the total of all the values consumed so far. When the loop completes, lines 3738 display a line indicating the sum of the consumed values. Then method `run` terminates, which indicates that the `Consumer` completed its task. Once both threads enter the *terminated* state, the program ends.

---

[Page 1066]

---

[Page 1067]

[*Note:* We use method `sleep` in method `run` of the `Producer` and `Consumer` classes to emphasize the fact that in multithreaded applications, it is unpredictable when each thread will perform its task and for how long it will perform the task when it has a processor. Normally, these thread-scheduling issues are the job of the computer's operating system and therefore beyond the control of the Java developer. In this program, our thread's tasks are quite simple: for the `Producer`, write the values 1 to 10 to the buffer, and for the `Consumer`, read 10 values from the buffer and add each value to variable `sum`. Without the `sleep` method call, and if the `Producer` executes first, given today's phenomenally fast processors, the `Producer` would likely complete its task before the `Consumer` gets a chance to execute. If the `Consumer` executes first, it would likely consume -1 ten times, then terminate before the `Producer` could produce the first real value.]

---

[Page 1068]

Class `UnsynchronizedBuffer` ([Fig. 23.9](#)) implements interface `Buffer` (line 4). An object of this class is shared between the `Producer` and the `Consumer`. Line 6 declares instance variable `buffer` and initializes it with the

value `-1`. This value is used to demonstrate the case in which the `Consumer` attempts to consume a value before the `Producer` ever places a value in `buffer`. Methods `set` (lines 913) and `get` (lines 1620) do not synchronize access to field `buffer`. Method `set` simply assigns its argument to `buffer` (line 12), and method `get` simply returns the value of `buffer` (line 19).

Class `SharedBufferTest` contains method `main` (lines 832), which launches the application. Line 11 creates an `ExecutorService` with two threads: one to execute the `Producer` and one to execute the `Consumer`. Line 14 creates an `UnsynchronizedBuffer` object and assigns its reference to `Buffer` variable `sharedLocation`. This object stores the data that will be shared between the `Producer` and `Consumer` threads. Lines 23-24 create and execute the `Producer` and `Consumer`. Note that the `Producer` and `Consumer` constructors are each passed the same `Buffer` object (`sharedLocation`), so each object is initialized with a reference to the same `Buffer`. These lines also implicitly launch the threads and call each `Runnable`'s `run` method. Finally, line 31 calls method `shutdown` so that the application can terminate when the `Producer` and `Consumer` threads complete their tasks. When method `main` terminates (line 32), the main thread of execution enters the *terminated* state.

Recall from the overview of this example that we would like the `Producer` thread to execute first and every value produced by the `Producer` to be consumed exactly once by the `Consumer`. However, when we study the first output of [Fig. 23.10](#), we see that the `Producer` writes a value three times before the `Consumer` reads its first value (3). Therefore, the values 1 and 2 are lost. Later, the values 5, 6 and 9 are lost, while 7 and 8 are read twice and 10 is read four times. So the first output produced an incorrect total of 77, instead of a correct total of 55. In the second output, note that the `Consumer` reads before the `Producer` ever writes a value. Also note that the `Consumer` has already read five times before the `Producer` writes the value 2. Meanwhile, the values 5, 7, 8, 9 and 10 are all lost. An incorrect output of 19 is produced. (Lines in the output where the `Producer` or `Consumer` has acted out of order are highlighted.) This example clearly demonstrates that access to a shared object by concurrent threads must be controlled carefully, for otherwise a program may produce incorrect results.

To solve the problems of lost and duplicated data, [Section 23.7](#) presents an example in which we use a `Lock` and `Condition` methods `await` and `signal` to synchronize access to the code that manipulates the shared object, guaranteeing that each and every value will be processed once and only once. When a thread acquires a lock, no other threads can acquire that same lock until the original thread releases it.

## 23.7. Producer/Consumer Relationship with Synchronization

The application in [Fig. 23.11](#) and [Fig. 23.12](#) demonstrates a producer and a consumer accessing a shared buffer with synchronization. In this case, the consumer correctly consumes only after the producer produces a value, and the producer correctly produces a new value only after the consumer consumes the previous value produced. We reuse interface `Buffer` ([Fig. 23.6](#)) and use classes `Producer` ([Fig. 23.7](#) modified to remove line 28) and `Consumer` ([Fig. 23.8](#) modified to remove line 28) from the example in [Section 23.6](#). This approach enables us to demonstrate that the threads accessing the shared object are unaware that they are being synchronized. The code that performs the synchronization is placed in the `set` and `get` methods of class `SynchronizedBuffer` ([Fig. 23.11](#)), which implements interface `Buffer` (line 7). Thus, the `Producer`'s and `Consumer`'s `run` methods simply call the shared object's `set` and `get` methods, as in the example in [Section 23.6](#).

| Producer writes 10                                         | 10 | true  |
| Producer done producing.<br>Terminating Producer.          |    |       |
| Consumer reads 10                                          | 10 | false |
| Consumer read values totaling 55.<br>Terminating Consumer. |    |       |

Class `SynchronizedBuffer` ([Fig. 23.11](#)) contains five fields. Line 10 creates a new object of type

`ReentrantLock` and assigns its reference to `Lock` variable `accessLock`. The `ReentrantLock` is created without the fairness policy because only a single `Producer` or `Consumer` will be waiting to acquire the `Lock` in this example. Lines 1314 create two `Conditions` using `Lock` method `newCondition`. `Condition canWrite` contains a queue for threads waiting while the buffer is full (i.e., there is data in the buffer that the `Consumer` has not read yet). If the buffer is full, the `Producer` calls method `await` on this `Condition`. When the `Consumer` reads data from a full buffer, it calls method `signal` on this `Condition`. `Condition canRead` contains a queue for threads waiting while the buffer is empty (i.e., there is no data in the buffer for the `Consumer` to read). If the buffer is empty, the `Consumer` calls method `await` on this `Condition`. When the `Producer` writes to the empty buffer, it calls method `signal` on this `Condition`. The `int buffer` (line 16) holds the shared data, and the `boolean` variable `occupied` (line 17) keeps track of whether the buffer currently holds data (that the `Consumer` should read) or not.

Line 22 in method `set` calls the `lock` method of the `SynchronizedBuffer`'s `accessLock`. If the lock is available (i.e., no other thread has acquired this lock), method `lock` will return immediately (this thread now owns the lock) and the thread will continue. If the lock is unavailable (i.e., the lock is held by another thread), this method will wait until the lock is released by the other thread. After the lock is acquired, the `try` block in lines 2545 executes. Line 28 tests `occupied` to determine whether the buffer is full. If it is, lines 3031 output that the thread will wait. Line 32 calls `Condition` method `await` on the `canWrite` condition variable which will temporarily release the `SynchronizedBuffer`'s lock and wait for a signal from the `Consumer` that the buffer is available for writing. When the buffer is available for writing, the method proceeds, writing to the buffer (line 35), setting `occupied` to `true` (line 39) and outputting that the producer wrote a value. Line 44 calls `Condition` method `signal` on condition variable `canRead` to notify the waiting `Consumer` that the buffer has new data to be read. Line 52 calls method `unlock` within a `finally` block to release the lock and allow the `Consumer` to proceed.

## Common Programming Error 23.3

*Place calls to `Lock` method `unlock` in a `finally` block. If an exception is thrown, `unlock` must still be called or deadlock could occur.*

Line 60 of method `get` (lines 5794) calls method `lock` to acquire the lock for this object. This method will wait until the lock is available. Once the lock is acquired, line 66 tests whether `occupied` is `false`, indicating that the buffer has no data. If the buffer is empty, line 70 calls method `await` on condition variable `canRead`. Recall that method `signal` is called on variable `canRead` in the `set` method (line 44). When the condition variable is signaled, the `get` method continues. Line 75 sets `occupied` to `false`, line 77 stores the value of `buffer` in `readValue` and line 78 outputs the `readValue`. Then line 81 signals the condition variable `canWrite`. This will awaken the `Producer` if it is indeed waiting for the buffer to be emptied. Line 90 calls method `unlock` in a `finally` block to release the lock, and line 93 returns the value of the buffer to the calling method.

## Software Engineering Observation 23.2

*Always invoke method `await` in a loop that tests an appropriate condition. It is possible that a thread will reenter the `runnable` state before the condition it was waiting on is satisfied. Testing the condition again ensures that the thread will not erroneously execute if it was signaled early.*

## Common Programming Error 23.4

*Forgetting to **signal** a thread that is waiting for a condition is a logic error. The thread will remain in the waiting state, which will prevent the thread from doing any further work. Such waiting can lead to indefinite postponement or deadlock.*

Class `SharedBufferTest2` ([Fig. 23.12](#)) is similar to class `SharedBufferTest` ([Fig. 23.10](#)). `SharedBufferTest2` contains method `main` (lines 830), which launches the application. Line 11 creates an `ExecutorService` with two threads to run the `Producer` and `Consumer`. Line 14 creates a `SynchronizedBuffer` object and assigns its reference to `Buffer` variable `sharedLocation`. This object stores the data that will be shared between the `Producer` and `Consumer` threads. Lines 1617 display the column heads for the output. Lines 2122 execute a `Producer` and a `Consumer`. Finally, line 29 calls method `shutdown` to end the application when the `Producer` and `Consumer` complete their tasks. When method `main` ends (line 30), the main thread of execution terminates.

Study the outputs in [Fig. 23.12](#). Observe that every integer produced is consumed exactly once, no values are lost, and no values are consumed more than once. The synchronization and condition variables ensure that the `Producer` and `Consumer` cannot perform their tasks unless it is their turn. The `Producer` must go first, the `Consumer` must wait if the `Producer` has not produced since the `Consumer` last consumed, and the `Producer` must wait if the `Consumer` has not yet consumed the value that the `Producer` most recently produced. Execute this program several times to confirm that every integer produced is consumed exactly once. In the sample output, note the lines indicating when the `Producer` and `Consumer` must wait to perform their respective tasks.

## 23.8. Producer/Consumer Relationship: Circular Buffer

The program in [Section 23.7](#) uses thread synchronization to guarantee that two threads manipulate data in a shared buffer correctly. However, the application may not perform optimally. If the two threads operate at different speeds, one of the threads will spend more (or most) of its time waiting. For example, in the program in [Section 23.7](#) we shared a single integer variable between the two threads. If the producer thread produces values faster than the consumer can consume them, then the producer thread waits for the consumer, because there are no other locations in memory in which to place the next value. Similarly, if the consumer consumes values faster than the producer produces them, the consumer waits until the producer places the next value in the shared location in memory. Even when we have threads that operate at the same relative speeds, those threads may occasionally become "out of sync" over a period of time, causing one of them to wait for the other. We cannot make assumptions about the relative speeds of concurrent threads; interactions that occur with the operating system, the network, the user and other components can cause the threads to operate at different speeds. When this happens, threads wait. When threads wait excessively, programs become less efficient, user-interactive programs become less responsive and applications suffer longer delays.

To minimize the amount of waiting time for threads that share resources and operate at the same average speeds, we can implement a [circular buffer](#) that provides extra buffer space into which the producer can place values and from which the consumer can retrieve those values. Let us assume that the buffer is implemented as an array. The producer and consumer work from the beginning of the array. When either thread reaches the end of the array, it simply returns to the first element of the array to perform its next task. If the producer temporarily produces values faster than the consumer can consume them, the producer can write additional values into the extra buffer space (if any are available). This capability enables the producer to perform its task even though the consumer is not ready to receive the current value being produced. Similarly, if the consumer consumes faster than the producer produces new values, the consumer can read additional values (if there are any) from the buffer. This enables the consumer to keep busy even though the producer is not ready to produce additional values.

Note that the circular buffer would be inappropriate if the producer and the consumer operate consistently at different speeds. If the consumer always executes faster than the producer, then a buffer containing one location is enough. Additional locations would waste memory. If the producer always executes faster, only a buffer with an infinite number of locations would be able to absorb the extra production.

The key to using a circular buffer with a producer and consumer that operate at about the same speed is to provide it with enough locations to handle the anticipated "extra" production. If, over a period of time, we determine that the producer often produces as many as three more values than the consumer can consume, we can provide a buffer of at least three cells to handle the extra production. We do not want the buffer to be too small, because that would cause threads to wait longer. On the other hand, we do not want the buffer to be too large, because that would waste memory.

### Performance Tip 23.4

*Even when using a circular buffer, it is possible that a producer thread could fill the buffer, which would force the producer thread to wait until a consumer consumes a value to free an element in the buffer. Similarly, if the buffer is empty at any given time, the consumer thread must wait until the producer produces another value. The key to using a circular buffer is to optimize the buffer size to minimize the amount of thread wait time.*

The program in [Fig. 23.13](#)[Fig. 23.14](#) demonstrates a producer and a consumer accessing a circular buffer (in this case, a shared array of three cells) with synchronization. In this version of the producer/consumer relationship, the consumer consumes a value only when the array is not empty and the producer produces a value only when the array is not full. The statements that created and started the thread objects in the `main` method of class `SharedBufferTest2` ([Fig. 23.12](#)) now appear in class `CircularBufferTest` ([Fig. 23.14](#)).

Producer done producing.
Terminating Producer.
Consumer reads 10 (buffers occupied: 0)
buffers: 10 8 9

 WR

Consumer read values totaling: 55.
Terminating Consumer.

```

The significant changes to the example in [Section 23.7](#) occur in `CircularBuffer` ([Fig. 23.13](#)), which replaces `SynchronizedBuffer` ([Fig. 23.11](#)). Line 10 creates a new `ReentrantLock` object and assigns its reference to `Lock` variable `accessLock`. The `ReentrantLock` is created without a fairness policy because we have only two threads in this example and only one will ever be waiting. Lines 13-14 create two `Conditions` using `Lock` method `newCondition`. `Condition canWrite` contains a queue for threads waiting while the buffer is full. If the buffer is full, the `Producer` calls method `await` on this `Condition` when the `Consumer` frees space in a full buffer, it calls method `signal` on this `Condition`. `Condition canRead` contains a queue for threads waiting while the buffer is empty. If the buffer is empty, the `Consumer` calls method `await` on this `Condition` when the `Producer` writes to the buffer, it calls method `signal` on this `Condition`. Array `buffer` (line 16) is a three-

element integer array that represents the circular buffer. Variable `occupiedBuffers` (line 18) counts the number of elements in `buffer` that are filled with data available to be read. When `occupiedBuffers` is 0, there is no data in the circular buffer and the `Consumer` must wait. When `occupiedBuffers` is 3 (the size of the circular buffer), the circular buffer is full and the `Producer` must wait. Variable `writeIndex` (line 19) indicates the next location in which a value can be placed by a `Producer`. Variable `readIndex` (line 20) indicates the position from which the next value can be read by a `Consumer`.

`CircularBuffer` method `set` (lines 2354) performs the same tasks that it did in [Fig. 23.11](#), with a few modifications. The `while` loop at lines 3135 determines whether the `Producer` must wait (i.e., all buffers are full). If so, line 33 indicates that the `Producer` is waiting to perform its task. Then line 34 invokes `Condition` method `await` to place the `Producer` thread in the *waiting* state on the `canWrite` condition variable. When execution eventually continues at line 37 after the `while` loop, the value written by the `Producer` is placed in the circular buffer at location `writeIndex`. Then line 40 updates `writeIndex` for the next call to `CircularBuffer` method `set`. This line is the key to the circularity of the buffer. When `writeIndex` is incremented past the end of the buffer, this line sets it to 0. Line 42 increments `occupiedBuffers`, because there is now at least one value in the buffer that the `Consumer` can read. Next, line 43 invokes method `displayState` to update the output with the value produced, the number of occupied buffers, the contents of the buffers and the current `writeIndex` and `readIndex`. Line 44 invokes `Condition` method `signal` to indicate that a `Consumer` thread waiting on the `canRead` condition variable (if there is a waiting thread) should transition to the *runnable* state. Line 52 releases `accessLock` by calling method `unlock` inside a `finally` block.

---

[Page 1081]

Method `get` (lines 5792) of class `CircularBuffer` also performs the same tasks as it did in [Fig. 23.11](#), with a few minor modifications. The `while` loop at lines 6670 determines whether the `Consumer` must wait (i.e., all buffers are empty). If the `Consumer` thread must wait, line 68 updates the output to indicate that the `Consumer` is waiting to perform its task. Then line 69 invokes `Condition` method `await` to place the current thread in the *waiting* state on the `canRead` condition variable. When execution eventually continues at line 72 after a `signal` call from the `Producer`, `readValue` is assigned the value at location `readIndex` in the circular buffer. Then line 75 updates `readIndex` for the next call to `CircularBuffer` method `get`. This line and line 40 create the circular effect of the buffer. Line 77 decrements the `occupiedBuffers`, because there is at least one open position in the buffer in which the `Producer` thread can place a value. Line 78 invokes method `displayState` to update the output with the consumed value, the number of occupied buffers, the contents of the buffers and the current `writeIndex` and `readIndex`. Line 79 invokes `Condition` method `signal` to transition the thread waiting to write into the `CircularBuffer` object into the *runnable* state. Line 88 releases `accessLock` inside a `finally` block to guarantee that the lock is released. Then line 91 returns the consumed value to the calling method.

Method `displayState` (lines 95122) outputs the state of the application. Lines 101102 output the current buffers. Line 102 uses method `printf` with a `%2d` format specifier to print the contents of each buffer with a leading space if it is a single digit. Lines 109119 output the current `writeIndex` and `readIndex` with the letters `W` and `R` respectively.

Class `CircularBufferTest` ([Fig. 23.14](#)) contains the `main` method that launches the application. Line 11 creates the `ExecutorService` with two threads, and line 14 creates a `CircularBuffer` object and assigns its reference to `Buffer` variable `sharedLocation`. Lines 1819 execute the `Producer` and `Consumer`. Line 26 calls method `shutdown` to end the application when the `Producer` and `Consumer` complete their tasks.

---

[Page 1084]

Each time the `Producer` writes a value or the `Consumer` reads a value, the program outputs the action performed (a read or a write) along with the contents of the buffer and the location of the write index and read index. In this output, the `Producer` first writes the value 1. The buffer then contains the value 1 in the first slot and the value -1 (the default value) in the other two slots. The write index is updated to the second slot, while the read index stays at the first slot. Next, the `Consumer` reads 1. The `buffer` contains the same values, but the read index has been updated to the second slot. The `Consumer` then tries to read again, but the buffer is empty and the `Consumer` is forced to wait. Note that only once in this execution of the program was it necessary for either thread to wait.

## 23.9. Producer/Consumer Relationship: ArrayBlockingQueue

J2SE 5.0 includes a fully-implemented circular buffer class named `ArrayBlockingQueue` in package `java.util.concurrent`, which implements the `BlockingQueue` interface. The `BlockingQueue` interface implements the `Queue` interface, discussed in [Chapter 19](#) and declares methods `put` and `take`, the blocking equivalents of `Queue` methods `offer` and `poll`, respectively. This means that method `put` will place an element at the end of the `BlockingQueue`, waiting if the queue is full. Method `take` will remove an element from the head of the `BlockingQueue`, waiting if the queue is empty. Class `ArrayBlockingQueue` implements the `BlockingQueue` interface using an array. This makes the data structure fixed size, meaning that it will not expand to accommodate extra elements. Class `ArrayBlockingQueue` encapsulates all the functionality of our circular buffer class ([Fig. 23.13](#)).

The program in [Fig. 23.15](#) demonstrates a `Producer` and a `Consumer` accessing a circular buffer (in this case, an `ArrayBlockingQueue`) with synchronization. Class `BlockingBuffer` implements interface `Buffer` ([Fig. 23.15](#)) and contains an `ArrayBlockingQueue` instance variable that stores `Integer` objects (line 7). By choosing to implement `Buffer`, our application can reuse the `Producer` ([Fig. 23.7](#)) and `Consumer` ([Fig. 23.8](#)) classes.

---

[Page 1085]

Figure 23.15. `BlockingBuffer` creates a blocking circular buffer using the `ArrayBlockingQueue` class.

```

1 // Fig. 23.15: BlockingBuffer.java
2 // Class synchronizes access to a blocking buffer.
3 import java.util.concurrent.ArrayBlockingQueue;
4
5 public class BlockingBuffer implements Buffer
6 {
7 private ArrayBlockingQueue<Integer> buffer;
8
9 public BlockingBuffer()
10 {
11 buffer = new ArrayBlockingQueue<Integer>(3);
12 } // end BlockingBuffer constructor
13
14 // place value into buffer
15 public void set(int value)
16 {
17 try
18 {
19 buffer.put(value); // place value in circular buffer
20 System.out.printf("%s%d\t%s%d\n", "Producer writes ", value,
21 "Buffers occupied: ", buffer.size());
22 } // end try
23 catch (Exception exception)
24 {
25 exception.printStackTrace();
26 } // end catch
27 } // end method set
28
29 // return value from buffer

```

```

30 public int get()
31 {
32 int readValue = 0; // initialize value read from buffer
33
34 try
35 {
36 readValue = buffer.take(); // remove value from circular buffer
37 System.out.printf("%s %2d\t%s%d\n", "Consumer reads ",
38 readValue, "Buffers occupied: ", buffer.size());
39 } // end try
40 catch (Exception exception)
41 {
42 exception.printStackTrace();
43 } // end catch
44
45 return readValue;
46 } // end method get
47 } // end class BlockingBuffer

```

Figure 23.16. **BlockingBufferTest** sets up a producer/consumer application using a blocking circular buffer.

(This item is displayed on pages 1086 - 1087 in the print version)

```

1 // Fig 23.16: BlockingBufferTest.java
2 // Application shows two threads manipulating a blocking buffer.
3 import java.util.concurrent.ExecutorService;
4 import java.util.concurrent.Executors;
5
6 public class BlockingBufferTest
7 {
8 public static void main(String[] args)
9 {
10 // create new thread pool with two threads
11 ExecutorService application = Executors.newFixedThreadPool(2);
12
13 // create BlockingBuffer to store ints
14 Buffer sharedLocation = new BlockingBuffer();
15
16 try // try to start producer and consumer
17 {
18 application.execute(new Producer(sharedLocation));
19 application.execute(new Consumer(sharedLocation));
20 } // end try
21 catch (Exception exception)
22 {
23 exception.printStackTrace();
24 } // end catch
25
26 application.shutdown();
27 } // end main
28 } // end class BlockingBufferTest

```

```
Producer writes 1 Buffers occupied: 1
Consumer reads 1 Buffers occupied: 0
Producer writes 2 Buffers occupied: 1
Consumer reads 2 Buffers occupied: 0
Producer writes 3 Buffers occupied: 1
Consumer reads 3 Buffers occupied: 0
Producer writes 4 Buffers occupied: 1
Consumer reads 4 Buffers occupied: 0
Producer writes 5 Buffers occupied: 1
Consumer reads 5 Buffers occupied: 0
Producer writes 6 Buffers occupied: 1
Consumer reads 6 Buffers occupied: 0
Producer writes 7 Buffers occupied: 1
Producer writes 8 Buffers occupied: 2
Consumer reads 7 Buffers occupied: 1
Producer writes 9 Buffers occupied: 2
Consumer reads 8 Buffers occupied: 1
Producer writes 10 Buffers occupied: 2

Producer done producing.
Terminating Producer.
Consumer reads 9 Buffers occupied: 1
Consumer reads 10 Buffers occupied: 0

Consumer read values totaling 55.
Terminating Consumer.
```

Line 19 in method `set` (lines 1527) calls method `put` on the `ArrayBlockingQueue`. This method call will block until there is room in `buffer` to place `value`. Method `get` (lines 3046) of class `BlockingBuffer` calls method `take` (line 36) on the `ArrayBlockingQueue`. Again, this method call will block until there is an element in `buffer` to remove. Note that neither of these methods requires a `Lock` or `Condition` object. The `ArrayBlockingQueue` handles all of the synchronization for you. The amount of code in this program is greatly decreased from the previous circular buffer (from 123 lines to 47 lines) and is much easier to understand. This is an excellent example of encapsulation and software reuse.

Class `BlockingBufferTest` (Fig. 23.16) contains the `main` method that launches the application. Line 11 creates the `ExecutorService`, and line 14 creates a `BlockingBuffer` object and assigns its reference to `Buffer` variable `sharedLocation`. Lines 1819 execute the `Producer` and `Consumer` `Runnables`. Line 26 calls method `shutdown` to end the application when the `Producer` and `Consumer` finish.

In our prior synchronization examples, the output statements in the `Buffer`'s `set` and `get` methods that indicated what the `Producer` was writing or the `Consumer` was reading were always executed while the `Buffer`'s lock was held by the thread calling `set` or `get`. This guaranteed the order in which the output would be displayed. If the `Consumer` had the lock, the `Producer` could not execute the `set` method; therefore, it was not possible for the `Producer` to output out of turn. The reverse was also true. In Fig. 23.15, methods `set` and `get` no longer use locks; all locking is handled by the `ArrayBlockingQueue`. Because this class is from the Java API, we cannot modify it to perform output from its `put` and `take` methods. For these reasons, it is possible that the `Producer` and `Consumer` output statements in this example could print out of order. Even though the `ArrayBlockingQueue` is properly synchronizing access to the data, the output statements are no longer synchronized.

## 23.10. Multithreading with GUI

This program uses separate threads to modify the content displayed in a Swing GUI. The nature of multithreaded programming prevents the programmer from knowing exactly when a thread will execute. Swing components are not **thread safe** if multiple threads manipulate a Swing GUI component, the results may not be correct. All interactions with Swing GUI components should be performed as part of the **event-dispatching thread** (also known as the **event-handling thread**). Class **SwingUtilities** (package `javax.swing`) provides **static** method **invokeLater** to help with this process. Method **invokeLater** specifies GUI processing statements to execute later as part of the event-dispatching thread. Method **invokeLater** receives as its argument an object that implements interface **Runnable**. The method places the **Runnable** as an event into the event-dispatching thread's queue of events. These events are processed in the order they appear in the queue. Because only one thread handles these events, it can be guaranteed that the GUI will be updated properly.

---

[Page 1088]

Our next example ([Fig. 23.17](#)) demonstrates this concept. When this program calls **invokeLater**, the GUI component update will be queued for execution in the event-dispatching thread. The **Runnable**'s **run** method will then be invoked as part of the event-dispatching thread to perform the output and ensure that the GUI component is updated in a thread-safe manner. This example also demonstrates how to **suspend** a thread (i.e., temporarily prevent it from executing) and how to **resume** a suspended thread.

Figure 23.17. **RunnableObject** outputs a random uppercase letter on a **JLabel**. Allows user to suspend and resume execution.

(This item is displayed on pages 1088 - 1090 in the print version)

```

1 // Fig. 23.17: RunnableObject.java
2 // Runnable that writes a random character to a JLabel
3 import java.util.Random;
4 import java.util.concurrent.locks.Condition;
5 import java.util.concurrent.locks.Lock;
6 import javax.swing.JLabel;
7 import javax.swing.SwingUtilities;
8 import java.awt.Color;
9
10 public class RunnableObject implements Runnable
11 {
12 private static Random generator = new Random(); // for random letters
13 private Lock lockObject; // application lock; passed in to constructor
14 private Condition suspend; // used to suspend and resume thread
15 private boolean suspended = false; // true if thread suspended
16 private JLabel output; // JLabel for output
17
18 public RunnableObject(Lock theLock, JLabel label)
19 {
20 lockObject = theLock; // store the Lock for the application
21 suspend = lockObject.newCondition(); // create new Condition
22 output = label; // store JLabel for outputting character
23 } // end RunnableObject constructor
24

```

```

25 // place random characters in GUI
26 public void run()
27 {
28 // get name of executing thread
29 final String threadName = Thread.currentThread().getName();
30
31 while (true) // infinite loop; will be terminated from outside
32 {
33 try
34 {
35 // sleep for up to 1 second
36 Thread.sleep(generator.nextInt(1000));
37
38 lockObject.lock(); // obtain the lock
39 try
40 {
41 while (suspended) // loop until not suspended
42 {
43 suspend.await(); // suspend thread execution
44 } // end while
45 } // end try
46 finally
47 {
48 lockObject.unlock(); // unlock the lock
49 } // end finally
50 } // end try
51 // if thread interrupted during wait/sleep
52 catch (InterruptedException exception)
53 {
54 exception.printStackTrace(); // print stack trace
55 } // end catch
56
57 // display character on corresponding JLabel
58 SwingUtilities.invokeLater(
59 new Runnable()
60 {
61 // pick random character and display it
62 public void run()
63 {
64 // select random uppercase letter
65 char displayChar =
66 (char) (generator.nextInt(26) + 65);
67
68 // output character in JLabel
69 output.setText(threadName + ": " + displayChar);
70 } // end method run
71 } // end inner class
72); // end call to SwingUtilities.invokeLater
73 } // end while
74 } // end method run
75
76 // change the suspended/running state
77 public void toggle()
78 {
79 suspended = !suspended; // toggle boolean controlling state
80
81 // change label color on suspend/resume
82 output.setBackground(suspended ? Color.RED : Color.GREEN);
83
84 lockObject.lock(); // obtain lock
85 try

```

```

86 {
87 if (!suspended) // if thread resumed
88 {
89 suspend.signal(); // resume thread
90 } // end if
91 } // end try
92 finally
93 {
94 lockObject.unlock(); // release lock
95 } // end finally
96 } // end method toggle
97 } // end class RunnableObject

```

Class `RunnableObject` (Fig. 23.17) implements interface `Runnable`'s `run` method (lines 2674). Line 29 uses static `Thread` method `currentThread` to determine the currently executing thread and `Thread` method `getName` to return the name of that thread. Every executing thread has a default name that includes the number of the thread (see the output of Fig. 23.18). Lines 3173 are an infinite loop. [*Note:* In earlier chapters we have said that infinite loops are bad programming because the application will not terminate. In this case, the infinite loop is in a separate thread from the main thread. When the application window is closed in this example, all the threads created by the main thread are closed as well, including threads (such as this one) that are executing infinite loops.] In each iteration of the loop, the thread `sleeps` for a random interval from 0 to 1 seconds (line 36).

Figure 23.18. `RandomCharacters` creates a `JFrame` with three `RunnableObjects` and three `JCheckBoxes` to allow the user to suspend and resume threads.

(This item is displayed on pages 1091 - 1093 in the print version)

82 application.setDefaultCloseOperation(EXIT_ON_CLOSE);
83 } // end main
84 } // end class RandomCharacters

```

[\[View full size image\]](#)

When the thread awakens, line 38 acquires the `Lock` on this application. Lines 41-44 `loop` while the `boolean` variable `suspended` is `TRUE`. Line 43 calls method `await` on `Condition suspend` to temporarily release the `Lock` and place this thread into the *waiting* state. When this thread is *signaled*, it reacquires the `Lock`, moves back to the *runnable* state and releases the `Lock` (line 48). When `suspended` is `false`, the thread should resume execution. If `suspended` is still `true`, the loop executes again.

---

[Page 1090]

Lines 5872 call `SwingUtilities` method `invokeLater`. Lines 5971 declare an anonymous inner class that implements the `Runnable` interface, and lines 6270 declare method `run`. The method call to `invokeLater` places this `Runnable` object in a queue to be executed by the event-dispatching thread. Lines 6566 create a random uppercase character. Line 69 calls method `setText` on the `JLabel output` to display the thread name and the random character on the `JLabel` in the application window.

When the user clicks the `JCheckBox` to the right of a particular `JLabel`, the corresponding thread should be suspended (temporarily prevented from executing) or resumed (allowed to continue executing). Suspending and resuming of a thread can be implemented by using thread synchronization and `Condition` methods `await` and `signal`. Lines 7796 declare method `toggle`, which will change the suspended/resumed state of the current thread. Line 79 reverses the value of `boolean` variable `suspended`. Line 82 changes the background color of the `JLabel` by calling method `setBackground`. If the thread is suspended, the background color will be `Color.RED`, whereas if the thread is running, the background color will be `Color.GREEN`. Method `toggle` is called from the event handler in [Fig. 23.18](#), so its tasks will be performed in the event-dispatch thread; thus, there is no need to use `invokeLater` for line 82. Line 84 acquires the `Lock` for this application. Line 87 then tests whether the thread was just resumed. If this is true, line 89 calls method `signal` on `Condition suspend`. This method call will alert a thread that was placed in the *waiting* state by the `await` method call in line 43. Line 94 releases the `Lock` on this application inside a `finally` block.

Note that the `if` statement in line 87 does not have an associated `else`. If this condition fails, it means that the thread has just been suspended. When this happens, a thread executing at line 38 will enter the `while` loop and line 43 will suspend the thread with a call to method `await`.

---

[Page 1091]

Class `RandomCharacters` ([Fig. 23.18](#)) displays three `JLabels` and three `JCheckBoxes`. A separate thread of execution is associated with each `JLabel` and `JCheckBox` pair. Each thread randomly displays letters from the alphabet in its corresponding `JLabel` object. Line 33 creates a new `ExecutorService` with method `newFixedThreadPool`. Lines 36-56 iterate three times. Lines 38-41 create and customize the `JLabel`. Line 44 creates the `JCheckBox`, and line 47 adds an `ActionListener` for each `JCheckBox` (this will be discussed later.) Lines 51-52 create a new `RunnableObject` implements the `Runnable` interface. Line 55 executes the `RunnableObject` with one of the threads of execution created in `runner` in line 33.

If the user clicks the `Suspended` checkbox next to a particular `JLabel`, the program invokes method `actionPerformed` (lines 6574) to determine which checkbox generated the event. Lines 68-73 determine which checkbox generated the event. Line 71 checks whether the source of the event is the `JCheckBox` in the current index. If it is, line 72 calls method `toggle` (lines 7592 of [Fig. 23.17](#)) on that `RunnableObject`.

---

[Page 1093]

## 23.11. Other Classes and Interfaces in `java.util.concurrent`

The `Runnable` interface provides only the most basic functionality for multithreaded programming. In fact, this interface has several limitations. Suppose a `Runnable` encounters a problem and tries to throw a checked exception. The `run` method is not declared to throw any exceptions, so the problem must be handled within the `Runnable`; the exception cannot be passed to the calling thread. Now suppose a `Runnable` is performing a long calculation and the application wants to retrieve the result of that calculation. The `run` method cannot return a value, so the application must use shared data to pass the value back to the calling thread. This also involves the overhead of synchronizing access to the data. The developers of the new concurrency APIs in J2SE 5.0 recognized these limitations and created a new interface to fix them. The `Callable` interface (package `java.util.concurrent`) declares a single method named `call`. This interface is designed to be similar to the `Runnable` interface, allowing an action to be performed concurrently in a separate thread, but the `call` method allows the thread to return a value or to throw a checked exception.

An application that creates a `Callable` likely wants to run the `Callable` concurrently with other `Runnable`s and `Callables`. The `ExecutorService` interface provides method `submit`, which will execute a `Callable` passed in as its argument. The `submit` method returns an object of type `Future` (package `java.util.concurrent`), which is an interface that represents the executing `Callable`. The `Future` interface declares method `get` to return the result of the `Callable` and provides other methods to manage a `Callable`'s execution.

## 23.12. Monitors and Monitor Locks

Another way to perform synchronization is to use Java's built-in **monitors**. Every object has a monitor. The monitor allows one thread at a time to execute inside a **synchronized statement** on the object. This is accomplished by acquiring a lock on the object when the program enters the **synchronized** statement. These statements are declared using the **synchronized** keyword with the form

```
synchronized (object)
{
 statements
} // end synchronized statement
```

---

[Page 1094]

where *object* is the object whose monitor lock will be acquired. If there are several **synchronized** statements trying to execute on an object at the same time, only one of them may be active on the object at once all the other threads attempting to enter a **synchronized** statement on the same object are placed in the *blocked* state.

The *blocked* state is not included in [Fig. 23.1](#), but it transitions to and from the *runnable* state. When a *runnable* thread must wait to enter a **synchronized** statement, it transitions to the *blocked* state. When the *blocked* thread enters the **synchronized** statement, it transitions to the *runnable* state.

When a **synchronized** statement finishes executing, the monitor lock on the object is released and the highest-priority *blocked* thread attempting to enter a **synchronized** statement proceeds. Java also allows **synchronized methods**. A **synchronized** method is equivalent to a **synchronized** statement enclosing the entire body of a method.

If a thread obtains the monitor lock on an object and then determines that it cannot continue with its task on that object until some condition is satisfied, the thread can call **Object** method **wait**, releasing the monitor lock on the object. The thread releases the monitor lock on the object and waits in the *waiting* state while the other threads try to enter the object's **synchronized** statement(s). When a thread executing a **synchronized** statement completes or satisfies the condition on which another thread may be waiting, it can call **Object** method **notify** to allow a waiting thread to transition to the *blocked* state again. At this point, the thread that transitioned from the *wait* state to the *blocked* state can attempt to reacquire the monitor lock on the object. Even if the thread is able to reacquire the monitor lock, it still might not be able to perform its task at this time in which case the thread will reenter the *waiting* state and release the monitor lock. If a thread calls **notifyAll**, then all the threads waiting for the monitor lock become eligible to reacquire the lock (that is, they all transition to the *blocked* state). Remember that only one thread at a time can obtain the monitor lock on the object other threads that attempt to acquire the same monitor lock will be *blocked* until the monitor lock becomes available again (i.e., until no other thread is executing in a **synchronized** statement on that object). Methods **wait**, **notify** and **notifyAll** are inherited by all classes from class **Object**.

### Software Engineering Observation 23.3

*The locking that occurs with the execution of **synchronized** methods could lead to deadlock if the locks are never released. When exceptions occur, Java's exception mechanism coordinates with Java's synchronization mechanism to release locks and avoid these kinds of deadlocks.*

## Common Programming Error 23.5

*It is an error if a thread issues a `wait`, a `notify` or a `notifyAll` on an object without having acquired a lock for it. This causes an `IllegalMonitorStateException`.*

The application in [Fig. 23.19](#) and [Fig. 23.20](#) demonstrates a producer and a consumer accessing a shared buffer with synchronization. In this case, the consumer consumes only after the producer produces a value, and the producer produces a new value only after the consumer consumes the value produced previously. In this example, we reuse interface `Buffer` ([Fig. 23.6](#)) and classes `Producer` ([Fig. 23.7](#)) and `Consumer` ([Fig. 23.8](#)) from the example in [Section 23.6](#). The code that performs the synchronization is placed in the `set` and `get` methods of class `SynchronizedBuffer` ([Fig. 23.19](#)), which implements interface `Buffer` (line 4). Thus, the `Producer`'s and `Consumer`'s run methods simply call the shared object's `set` and `get` methods, as in the example in [Section 23.6](#).

Figure 23.19. Synchronizes access to shared data using `Object` methods `wait` and `notify`.

(This item is displayed on pages 1095 - 1096 in the print version)

```
1 // Fig. 23.19: SynchronizedBuffer.java
2 // SynchronizedBuffer synchronizes access to a single shared integer.
3
4 public class SynchronizedBuffer implements Buffer
5 {
6 private int buffer = -1; // shared by producer and consumer threads
7 private boolean occupied = false; // count of occupied buffers
8
9 // place value into buffer
10 public synchronized void set(int value)
11 {
12 // while there are no empty locations, place thread in waiting state
13 while (occupied)
14 {
15 // output thread information and buffer information, then wait
16 try
17 {
18 System.out.println("Producer tries to write.");
19 displayState("Buffer full. Producer waits.");
20 wait();
21 } // end try
22 catch (InterruptedException exception)
23 {
24 exception.printStackTrace();
25 } // end catch
26 } // end while
27
28 buffer = value; // set new buffer value
29 }
```

```

30 // indicate producer cannot store another value
31 // until consumer retrieves current buffer value
32 occupied = true;
33
34 displayState("Producer writes " + buffer);
35
36 notify(); // tell waiting thread to enter runnable state
37 } // end method set; releases lock on SynchronizedBuffer
38
39 // return value from buffer
40 public synchronized int get()
41 {
42 // while no data to read, place thread in waiting state
43 while (!occupied)
44 {
45 // output thread information and buffer information, then wait
46 try
47 {
48 System.out.println("Consumer tries to read.");
49 displayState("Buffer empty. Consumer waits.");
50 wait();
51 } // end try
52 catch (InterruptedException exception)
53 {
54 exception.printStackTrace();
55 } // end catch
56 } // end while
57
58 // indicate that producer can store another value
59 // because consumer just retrieved buffer value
60 occupied = false;
61
62 int readValue = buffer; // store value in buffer
63 displayState("Consumer reads " + readValue);
64
65 notify(); // tell waiting thread to enter runnable state
66
67 return readValue;
68 } // end method get; releases lock on SynchronizedBuffer
69
70 // display current operation and buffer state
71 public void displayState(String operation)
72 {
73 System.out.printf("%-40s%d\t\t%b\n\n", operation, buffer,
74 occupied);
75 } // end method displayState
76 } // end class SynchronizedBuffer

```

| Buffer empty. Consumer waits.     | 7  | false |
| Producer writes 8                 | 8  | true  |
| Consumer reads 8                  | 8  | false |
| Producer writes 9                 | 9  | true  |
| Producer tries to write.          |    |       |
| Buffer full. Producer waits.      | 9  | true  |
| Consumer reads 9                  | 9  | false |
| Producer writes 10                | 10 | true  |
| Producer done producing.          |    |       |
| Terminating Producer.             |    |       |
| Consumer reads 10                 | 10 | false |
| Consumer read values totaling 55. |    |       |
| Terminating Consumer.             |    |       |

Class `SynchronizedBuffer` (Fig. 23.19) contains two fields `buffer` (line 6) and `occupied` (line 7). Method `set` (lines 1037) and method `get` (lines 4068) are declared as `synchronized` methods by adding the `synchronized` keyword between the method modifier and the return type; thus, only one thread can call any of these methods at a time on a particular `SynchronizedBuffer` object. Field `occupied` is used in conditional expressions to determine whether it is the producer's or the consumer's turn to perform a task. If `occupied` is `false`, `buffer` is empty and the producer can call method `set` to place a value into variable `buffer`. This condition also means that the consumer cannot call `SynchronizedBuffer`'s `get` method to read the value of `buffer` because it is empty. If `occupied` is `True`, the consumer can call `SynchronizedBuffer`'s `get` method to read a value from variable `buffer`, because the variable contains new information. This condition also means that the producer cannot call `SynchronizedBuffer`'s `set` method to place a value into `buffer`, because the buffer is currently full.

When the `Producer` thread's `run` method invokes synchronized method `set`, the thread attempts to acquire

the monitor lock on the `SynchronizedBuffer` object. If the monitor lock is available, the `Producer` thread acquires the lock. Then the while loop at lines 1326 determines whether `occupied` is `true`. If so, the buffer is full, so line 18 outputs a message indicating that the `Producer` thread is trying to write a value, and line 19 invokes method `displayState` (lines 7175) to output another message indicating that the buffer is full and that the `Producer` thread is in the *waiting* state. Line 20 invokes method `wait` (inherited from `Object` by `SynchronizedBuffer`) to place the thread that called method `set` (i.e., the `Producer` thread) in the *waiting* state for the `SynchronizedBuffer` object. The call to `wait` causes the calling thread to release the lock on the `SynchronizedBuffer` object. This is important because the thread cannot currently perform its task and because other threads should be allowed to access the object at this time to allow the condition (`occupied`) to change. Now another thread can attempt to acquire the `SynchronizedBuffer` object's lock and invoke the object's `set` or `get` method.

---

[Page 1097]

The producer thread remains in the *waiting* state until the thread is notified by another thread that it may proceed at which point the producer thread returns to the *blocked* state and attempts to reacquire the lock on the `SynchronizedBuffer` object. If the lock is available, the producer thread reacquires the lock, and method `set` continues executing with the next statement after `wait`. Because `wait` is called in a loop (lines 1326), the loop-continuation condition is tested again to determine whether the thread can proceed with its execution. If not, `wait` is invoked again; otherwise, method `set` continues with the next statement after the loop.

Line 28 in method `set` assigns `value` to `buffer`. Line 32 sets `occupied` to `true` to indicate that the `buffer` now contains a value (i.e., a consumer can read the value, and a producer cannot yet put another value there). Line 34 invokes method `displayState` to output a line to the console window indicating that the producer is writing a new value into the `buffer`. Line 36 invokes method `notify` (inherited from `Object`). If there are any waiting threads, the first one enters the *blocked* state, indicating that the thread can now attempt to acquire the lock again. Method `notify` returns immediately and method `set` returns to its caller. Invoking method `notify` works correctly in this program because only one thread calls method `get` at any time (the `ConsumerThread`). In programs that have multiple threads waiting on a condition, it may be more appropriate to use method `notifyAll` or call method `wait` with an optional timeout. When method `set` returns, it implicitly releases the lock on the shared memory.

Methods `get` and `set` are implemented similarly. When the `Consumer` thread's `run` method invokes synchronized method `get`, the thread attempts to acquire the monitor lock on the `SynchronizedBuffer` object. If the lock is available, the `Consumer` thread acquires it. Then the while loop at lines 4356 determines whether `occupied` is `false`. If so, the buffer is empty, so line 48 outputs a message indicating that the `Consumer` thread is trying to read a value, and line 49 invokes method `displayState` to output another message indicating that the buffer is empty and that the `Consumer` thread is waiting. Line 50 invokes method `wait` to place the thread that called method `get` (i.e., the `Consumer` thread) in the *waiting* state for the `SynchronizedBuffer` object. Again, the call to `wait` causes the calling thread to release the lock on the `SynchronizedBuffer` object, so another thread can attempt to acquire the `SynchronizedBuffer` object's lock and invoke the object's `set` or `get` method. If the lock on the `SynchronizedBuffer` is not available (e.g., if the `ProducerThread` has not yet returned from method `set`), the `ConsumerThread` is blocked until the lock becomes available.

The consumer thread object remains in the *waiting* state until the thread is notified by another thread that it may proceed at which point the consumer thread returns to the *blocked* state and attempts to reacquire the lock on the `SynchronizedBuffer` object. If the lock is available, the consumer thread reacquires the lock and method `get` continues executing with the next statement after `wait`. Because `wait` is called in a loop (lines 4356), the loop-continuation condition is tested again to determine whether the thread can proceed with its execution. If not, `wait` is invoked again; otherwise, method `get` continues with the next statement after the loop. Line 60 sets `occupied` to `false` to indicate that `buffer` is now empty (i.e., a consumer cannot read the value, but a producer can place another value into `buffer`), line 63 calls method `displayState` to indicate that the consumer is reading and line 65 invokes method `notify`. If there are any threads in the *blocked* state for the lock on this `SynchronizedBuffer` object, one of them enters the *runnable* state, indicating that the thread can now attempt to reacquire the lock and continue performing its task. Method `notify` returns immediately, then method `get` returns the value of `buffer` to its caller. Invoking method `notify` works correctly in this program because only one thread calls method `set` at any time (the `ProducerThread`). Programs that have multiple threads waiting on a condition should invoke `notifyAll` to ensure that multiple

threads receive notifications properly. When method `get` returns, the lock on the `SynchronizedBuffer` object is implicitly released.

---

[Page 1098]

Class `SharedBufferTest2` ([Fig. 23.20](#)) is identical to class `SharedBufferTest` ([Fig. 23.12](#)). Study the outputs in [Fig. 23.20](#). Observe that every integer produced is consumed exactly once; no values are lost, and no values are consumed more than once. The synchronization and condition variable ensure that the producer and consumer cannot perform their tasks unless it is their turn. The producer must go first, the consumer must wait if the producer has not produced since the consumer last consumed, and the producer must wait if the consumer has not yet consumed the value that the producer most recently produced. Execute this program several times to confirm that every integer produced is consumed exactly once. In the sample output, note the lines indicating when the producer and consumer must wait to perform their respective tasks.

## 23.13. Wrap-Up

This chapter presented Java's new concurrency API and demonstrated the powerful technique of thread synchronization. Multithreading is an advanced topic that is the subject of many books. We use the multithreading techniques introduced here again in [Chapter 24](#), Networking, to help build multithreaded servers that can interact with multiple clients concurrently.

## Summary

- Computers perform operations concurrently, such as compiling programs, sending files to a printer and receiving electronic mail messages over a network.
  - Programming languages generally provide a set of control statements that only enable programmers to perform one action at a time.
  - Historically, concurrency has been implemented as operating-system primitives available only to experienced systems programmers.
  - Java makes concurrency available to the applications programmer. The programmer specifies that applications contain threads of execution each thread designating a portion of a program that may execute concurrently with other threads. This capability is called multithreading.
  - A new thread begins its life cycle in the *new* state. It remains in the *new* state until the program starts the thread, which places the thread in the *runnable* state.
  - A *runnable* thread enters the *terminated* state when it completes its task or otherwise terminates.
- 

[Page 1101]

- Sometimes a thread transitions to the *waiting* state while it waits for another thread to perform a task. Once in this state, a thread transitions back to the *runnable* state only when another thread signals the waiting thread to continue executing.
- A *runnable* thread can enter the *timed waiting* state for a specified interval of time. A thread in this state transitions back to the *runnable* state when that time interval expires. A thread can transition to the *timed waiting* state if it provides an optional wait interval when it is waiting for another thread to perform a task. Such a thread will return to the *runnable* state when it is signaled by another thread or when the timed interval expires whichever comes first. Another way to place a thread in the *timed waiting* state is to put the thread to sleep.
- At the operating system level, the *runnable* state actually encompasses two separate states. When a thread first transitions to the *runnable* state from the *new* state, the thread is in the *ready* state. A *ready* thread enters the *running* state (i.e., begins executing) when the operating system assigns the thread to a processor. When the thread's quantum expires, the thread returns to the *ready* state, and the operating system assigns to the processor another thread.
- Every Java thread has a priority in the range between `MIN_PRIORITY` (1) and `MAX_PRIORITY` (10). By default, each thread is given priority `NORM_PRIORITY` (5).
- Most Java platforms support timeslicing. Without timeslicing, each thread in a set of equal-priority threads runs to completion before other equal priority threads get a chance to execute. With timeslicing, each thread receives a brief burst of processor time, or quantum, during which the thread can execute. When the quantum expires, even if the thread has not finished executing, the processor is taken away from it and given to the next thread of equal priority, if one is available.
- The thread scheduler determines which thread runs next. One simple implementation will keep the highest-priority thread running at all times. If there is more than one highest-priority thread, the scheduler ensures that all such threads execute for a quantum each in round-robin fashion.
- Multithreading in Java is accomplished by implementing the `Runnable` interface, which declares a single method named `run`.

- `Runnable` are executed using a class that implements the `Executor` interface, which declares a single method named `execute`.
- Interface `ExecutorService` is a subinterface of `Executor` that declares several methods for managing the life cycle of the `Executor`. An object that implements the `ExecutorService` interface can be created using `static` methods declared in class `Executors`.
- `ExecutorService` method `shutdown` ends each thread in an `ExecutorService` as soon as it finishes executing its `Runnable`.
- When multiple threads share an object, indeterminate results may occur unless the shared object is synchronization properly. Mutual exclusion allows the programmer to perform such thread synchronization.
- Once a `Lock` has been obtained by a thread (by calling the `lock` method), the `Lock` object will not allow another thread to obtain the lock until the first thread releases the `Lock` (by calling the `unlock` method). When a thread calls method `unlock`, the lock on the object is released and the highest-priority waiting thread attempting to lock the object proceeds.
- Once a thread obtains the lock on an object, if the thread determines that it cannot continue with its task until some condition is satisfied, the thread can wait on a condition variable, thus removing it from contention for the processor and releasing the lock on the object. Condition variables are created by calling `Lock` method `newCondition`, which returns a `Condition` object.
- A thread can call method `await` on a `Condition` object to release the associated `Lock` and place that thread in the *waiting* state while other threads try to obtain the `Lock`. When another thread satisfies the condition on which the first thread is *waiting*, that thread can call `Condition` method `signal` to allow the waiting thread to transition to the *runnable* state again. If a thread calls `Condition` method `signalAll`, then all the threads waiting for the lock become eligible to reacquire the lock. Only one of those threads can obtain the lock on the object at a time; other threads that attempt to acquire the same lock will have to wait until the lock becomes available again.

---

[Page 1102]

- In a producer/consumer relationship, the producer portion of an application generates data and stores it in a shared object, and the consumer portion of an application reads data from the shared object. In a multithreaded producer/consumer relationship, a producer thread generates data and places it in a shared object called a buffer. A consumer thread reads data from the buffer.
- To minimize the amount of waiting time for threads that share resources and operate at the same average speeds, use a circular buffer that provides extra buffer space into which the producer can place values and from which the consumer can retrieve those values.
- The `BlockingQueue` interface declares methods `put` and `take`, which are the blocking equivalents of `Queue` methods `offer` and `remove`, respectively. This means that method `put` will place an element at the end of the `BlockingQueue`, waiting if the queue is full. Method `take` will remove an element from the head of the `BlockingQueue`, waiting if the queue is empty. Class `ArrayBlockingQueue` implements the `BlockingQueue` interface using an array. This makes the data structure fixed size, meaning that it will not expand to accommodate extra elements.
- Swing components are not thread safe if multiple threads manipulate a Swing GUI component, the results may not be correct. All interactions with Swing GUI components should be performed in the event-dispatch thread. Class `SwingUtilities` provides `static` method `invokeLater` to help with this process. Method `invokeLater` receives as its argument an object that implements interface `Runnable` and performs the GUI updates.
- The `Callable` interface declares a single method named `call` which allows the user to return a value or throw a checked exception. The `ExecutorService` interface provides method `submit` which will execute a `Callable` passed in as its argument. The `submit` method returns an object of type `Future` which is an interface that represents the executing `Callable`. The `Future` interface declares method `get` to return the result of the `Callable` and provides other methods to manage the execution of the `Callable`.

- An object's monitor allows one thread at a time to execute inside a `synchronized` statement on that object.
- When a *runnable* thread must wait to enter a `synchronized` statement, it transitions to the *blocked* state. When the *blocked* thread enters the `synchronized` statement, it transitions to the *runnable* state.
- Java also allows `synchronized` methods which is equivalent to a `synchronized` statement that encloses the entire body of the method.
- Once a thread obtains the monitor lock on an object, if the thread determines that it cannot continue with its task on that object until some condition is satisfied, the thread can call `Object` method `wait`, releasing the monitor lock on the object.
- When a thread executing a `synchronized` statement completes or satisfies the condition on which another thread may be waiting, the thread can call `Object` method `notify` to allow a waiting thread to transition to the *blocked* state again.
- If a thread calls `notifyAll`, then all threads waiting for the monitor lock become eligible to reacquire the lock (that is, they all transition to the *blocked* state).

## Self-Review Exercises

23.1 Fill in the blanks in each of the following statements:

- a. C and C++ are \_\_\_\_\_ -threaded languages, whereas Java is a(n) \_\_\_\_\_ -threaded language.

---

[Page 1104]

- b. A thread enters the *terminated* state when \_\_\_\_\_.
- c. To pause for a designated number of milliseconds and resume execution, a thread should call method \_\_\_\_\_.
- d. Method \_\_\_\_\_ of class `Condition` moves a single thread in an object's *waiting* state to the *runnable* state.
- e. Method \_\_\_\_\_ of class `Condition` moves every thread in an object's *waiting* state to the *runnable* state.
- f. A(n) \_\_\_\_\_ thread enters the \_\_\_\_\_ state when it completes its task or otherwise terminates.
- g. A *runnable* thread can enter the \_\_\_\_\_ state for a specified interval of time.
- h. At the operating-system level, the *runnable* state actually encompasses two separate states, \_\_\_\_\_ and \_\_\_\_\_.
- i. `Runnable`s are executed using a class that implements the \_\_\_\_\_ interface.
- j. `ExecutorService` method \_\_\_\_\_ ends each thread in an `ExecutorService` as soon as it finishes executing its current `Runnable`, if any.
- k. A thread can call method \_\_\_\_\_ on a `Condition` object to release the associated `Lock` and place that thread in the \_\_\_\_\_ state.
- l. In a(n) \_\_\_\_\_ relationship, the \_\_\_\_\_ portion of an application generates data and stores it in a shared object, and the \_\_\_\_\_ portion of an application reads data from the shared object.
- m. To minimize the amount of waiting time for threads that share resources and operate at the same average speeds, use a(n) \_\_\_\_\_.
- n. Class \_\_\_\_\_ implements the `BlockingQueue` interface using an array.
- o. The keyword \_\_\_\_\_ indicates that only one thread at a time should execute on an object.

23.2 State whether each of the following is *true* or *false*. If *false*, explain why.

- a. A thread is not *runnable* if it is dead.

- b. In Java, a higher-priority *runnable* thread should preempt threads of lower priority.
- c. Some operating systems use timeslicing with threads. Therefore, they can enable threads to preempt threads of the same priority.
- d. When the thread's quantum expires, the thread returns to the *running* state as the operating system assigns the thread to a processor.
- e. Without timeslicing, each thread in a set of equal-priority threads runs to completion before other threads of equal priority get a chance to execute.

## Answers to Self-Review Exercises

[23.1](#) a) single, multi. b) its `run` method ends. c) `Thread.sleep`. d) `signal`. e) `signalAll`. f) *runnable, terminated*. g) *timed waiting*. h) *ready, running*. i) `Executor`. j) `shutdown`. k) *await, waiting*. l) producer/consumer, producer, consumer. m) circular buffer. n) `ArrayBlockingQueue`. o) `synchronized`.

[23.2](#) a) True. b) True. c) False. Timeslicing allows a thread to execute until its timeslice (or quantum) expires. Then other threads of equal priority can execute. d) False. When a thread's quantum expires, the thread returns to the *ready* state and the operating system assigns to the processor another thread. e) True.

## Exercises

23.3 State whether each of the following is *true* or *false*. If *false*, explain why.

- a. Method `sleep` does not consume processor time while a thread sleeps.

---

[Page 1105]

- b. Using a `Lock` guarantees that deadlock cannot occur.
- c. Once a `Lock` has been obtained by a thread, the `Lock` object will not allow another thread to obtain the lock until the first thread releases it.
- d. Swing components are thread safe.

23.4 Define each of the following terms.

- a. thread
- b. multithreading
- c. *runnable* state
- d. *timed waiting* state
- e. preemptive scheduling
- f. `Runnable` interface
- g. `signal` method of class `Condition`
- h. producer/consumer relationship
- i. quantum

23.5 Discuss each of the following terms in the context of Java's threading mechanisms:

- a. `Lock`
- b. producer
- c. consumer
- d. `await`
- e. `signal`
- f. `Condition`

- 23.6 Two problems that can occur in systems like Java, that allow threads to wait, are deadlock, in which one or more threads will wait forever for an event that cannot occur, and indefinite postponement, in which one or more threads will be delayed for some unpredictably long time. Give an example of how each of these problems can occur in a multithreaded Java program.
- 23.7
- 23.8 Discuss the difference between `Condition` method `await` with no arguments and `Condition` method `await` with a time-interval argument. In particular, what states do threads enter, and how can those threads return to the runnable state?
- 23.9 Name three threads that are created automatically by the Java virtual machine and discuss the purpose of each thread.
- 23.10 Write a program that bounces a blue ball inside a `JPanel`. The ball should begin moving with a `mousePressed` event. When the ball hits the edge of the `JPanel`, it should bounce off the edge and continue in the opposite direction. The ball should be updated using a `Runnable`.
- 23.11 Modify the program in [Exercise 23.10](#) to add a new ball each time the user clicks the mouse. Provide for a minimum of 20 balls. Randomly choose the color for each new ball.
- 23.12 Modify the program in [Exercise 23.11](#) to add shadows. As a ball moves, draw a solid black oval at the bottom of the `JPanel`. You may consider adding a 3-D effect by increasing or decreasing the size of each ball when it hits the edge of the `JPanel`.
- 23.13 Modify the program in [Exercise 23.11](#) or [Exercise 23.12](#) to bounce the balls off each other when they collide. A collision should occur between two balls when the distance between the centers of those two balls is less than the sum of the two balls' radii.

# Chapter 24. Networking

*If the presence of electricity can be made visible in any part of a circuit, I see no reason why intelligence may not be transmitted instantaneously by electricity.*

Samuel F. B. Morse

*Protocol is everything.*

Francois Giuliani

*What networks of railroads, highways and canals were in another age, the networks of telecommunications, information and computerization ... are today.*

Bruno Kreisky

*The port is near, the bells I hear, the people all exulting.*

Walt Whitman

## OBJECTIVES

In this chapter you will learn:

- To understand Java networking with URLs, sockets and datagrams.
- To implement Java networking applications by using sockets and datagrams.
- To understand how to implement Java clients and servers that communicate with one another.
- To understand how to implement network-based collaborative applications.
- To construct a multithreaded server.

## Outline

[24.1](#) Introduction

[24.2](#) Manipulating URLs

[24.3](#) Reading a File on a Web Server

## 24.1. Introduction

There is much excitement about the Internet and the World Wide Web. The Internet ties the information world together. The World Wide Web makes the Internet easy to use and gives it the flair and sizzle of multimedia. Organizations see the Internet and the Web as crucial to their information-systems strategies. Java provides a number of built-in networking capabilities that make it easy to develop Internet-based and Web-based applications. Java can enable programs to search the world for information and to collaborate with programs running on other computers internationally, nationally or just within an organization. Java can enable applets and applications to communicate with one another (subject to security constraints).

Networking is a massive and complex topic. Computer science and computer engineering students will typically take a full-semester, upper-level course in computer networking and continue with further study at the graduate level. Java is often used as an implementation vehicle in computer networking courses. In *Java How to Program, Sixth Edition*, we introduce a portion of Java's networking concepts and capabilities. We discuss more advanced networking capabilities in our book *Advanced Java 2 Platform How to Program*.

Java's fundamental networking capabilities are declared by classes and interfaces of package `java.net`, through which Java offers [stream-based communications](#) that enable applications to view networking as streams of data. The classes and interfaces of package `java.net` also offer [packet-based communications](#) for transmitting individual [packets](#) of information commonly used to transmit audio and video over the Internet. In this chapter, we show how to create and manipulate sockets and how to communicate with packets and streams of data.

Our discussion of networking focuses on both sides of the [client-server relationship](#). The [client](#) requests that some action be performed, and the [server](#) performs the action and responds to the client. A common implementation of the request-response model is between Web browsers and Web servers. When a user selects a Web site to browse through a browser (the client application), a request is sent to the appropriate Web server (the server application). The server normally responds to the client by sending an appropriate HTML Web page.

We introduce Java's [socket-based communications](#), which enable applications to view networking as if it were file I/O: a program can read from a [socket](#) or write to a socket as simply as reading from a file or writing to a file. The socket is simply a software construct that represents one endpoint of a connection. We show how to create and manipulate stream sockets and datagram sockets.

With [stream sockets](#), a process establishes a [connection](#) to another process. While the connection is in place, data flows between the processes in continuous [streams](#). Stream sockets are said to provide a [connection-oriented service](#). The protocol used for transmission is the popular [TCP](#) ([Transmission Control Protocol](#)).

With [datagram sockets](#), individual [packets](#) of information are transmitted. This is not appropriate for everyday programmers, because the protocol used, [UDP](#), the [User Datagram Protocol](#) is a [connectionless service](#), and thus does not guarantee that packets arrive in any particular order. With UDP, packets can even be lost or duplicated. Significant extra programming is required on the programmer's part to deal with these problems (if the programmer chooses to do so). UDP is most appropriate for network applications that do not require the error checking and reliability of TCP. Stream sockets and the TCP protocol will be more desirable for the vast majority of Java programmers.

*Connectionless services generally offer greater performance but less reliability than connection-oriented services.*

## Portability Tip 24.1

*TCP, UDP and related protocols enable a great variety of heterogeneous computer systems (i.e., computer systems with different processors and different operating systems) to intercommunicate.*

The chapter includes a case study in which we implement a client/server chat application similar to the instant-messaging services popular on the Web today. The application incorporates many networking techniques introduced in this chapter. It also introduces [multicasting](#), in which a server can [publish](#) information and clients can [subscribe](#) to that information. Each time the server publishes more information, all subscribers receive it. Throughout the examples of this chapter, we will see that many of the networking details are handled by the Java APIs.

[◀ PREV](#)[NEXT ▶](#)

## 24.2. Manipulating URLs

The Internet offers many protocols. The [Hypertext Transfer Protocol \(HTTP\)](#), which forms the basis of the World Wide Web, uses [URIs \(Uniform Resource Identifiers\)](#) to identify data on the Internet. URIs that specify the locations of documents are called [URLs \(Uniform Resource Locators\)](#). Common URLs refer to files or directories and can reference objects that perform complex tasks, such as database lookups and Internet searches. If you know the HTTP URL of a publicly available HTML document anywhere on the Web, you can access it through HTTP.

Java makes it easy to manipulate URLs. When you use a URL that refers to the exact location of a resource (e.g., a Web page) as an argument to the `showDocument` method of interface `AppletContext`, the browser in which the applet is executing will display that resource. The applet in [Fig. 24.1](#) and [Fig. 24.2](#) demonstrates simple networking capabilities. It enables the user to select a Web page from a `JList` and causes the browser to display the corresponding page. In this example, the networking is performed by the browser.

85
86 counter++;
87 title = getParameter("title" + counter); // get next site title
88 } // end while
89 } // end method getSitesFromHTMLParameters
90 } // end class SiteSelector

```

[\[View full size image\]](#)

This applet takes advantage of [applet parameters](#) specified in the HTML document that invokes the applet. When browsing the World Wide Web, you will often come across applets that are in the public domain; you can use them free of charge on your own Web pages (normally in exchange for crediting the applet's creator). Many applets can be customized via parameters supplied from the HTML file that invokes the applet. For example, [Fig. 24.1](#) contains the HTML that invokes the applet `SiteSelector` in [Fig. 24.2](#).

The HTML document contains eight parameters specified with the `param` tag; these lines must appear between the starting and ending `applet` tags. The applet can read these values and use them to customize itself. Any number of `param` tags can appear between the starting and ending `applet` tags. Each parameter has a **name** and a **value**. Applet method `getParameter` retrieves the **value** associated with a specific parameter name and returns it as a string. The argument passed to `getParameter` is a string containing the name of the parameter in the `param` element. In this example, parameters represent the title and location of each Web site the user can select. Parameters specified for this applet are named `title#`, where the value of `#` starts at 0 and increments by 1 for each new title. Each title should have a corresponding location parameter of the form `location#`, where the value of `#` starts at 0 and increments by 1 for each new location. The statement

```
String title = getParameter("title0");
```

gets the value associated with parameter `"title0"` and assigns it to reference `title`. If there is no `param` tag containing the specified parameter, `getParameter` returns `null`.

The applet ([Fig. 24.2](#)) obtains from the HTML document ([Fig. 24.1](#)) the choices that will be displayed in the applet's `JList`. Class `SiteSelector` uses a `HashMap` (package `java.util`) to store the Web site names and URLs. In this example, the *key* is the string in the `JList` that represents the Web site name, and the *value* is a `URL` object that stores the location of the Web site to display in the browser.

---

[Page 1110]

Class `SiteSelector` also contains an `ArrayList` (package `java.util`) in which the site names are placed so that they can be used to initialize the `JList` (one version of the `JList` constructor receives an array of `Objects` which is returned by `ArrayList`'s `toArray` method). An `ArrayList` is a dynamically resizable array of references. Class `ArrayList` provides method `add` to add a new element to the end of the `ArrayList`. (We provide discussions of classes `ArrayList` and `HashMap` in [Chapter 19](#).)

Lines 2526 in the applet's `init` method (lines 2357) create a `HashMap` object and an `ArrayList` object. Line 29 calls our utility method `getSitesFromHTMLParameters` (declared at lines 6089) to obtain the HTML parameters from the HTML document that invoked the applet.

---

[Page 1112]

In method `getSitesFromHTMLParameters`, line 67 uses Applet method `getParameter` to obtain a Web site title. If the `title` is not `null`, the loop at lines 7088 begins executing. Line 73 uses Applet method `getParameter` to obtain the Web site location. Line 77 uses the `location` as the value of a new `URL` object. The `URL` constructor determines whether its argument represents a valid URL. If not, the `URL` constructor throws a `MalformedURLException`. Note that the `URL` constructor must be called in a `try` block. If the `URL` constructor generates a `MalformedURLException`, the call to `printStackTrace` (line 83) causes the program to output a stack trace to the Java console. On Windows machines, the Java console can be viewed by right clicking the Java icon in the notification area of the taskbar. Then the program attempts to obtain the next Web site title. The program does not add the site for the invalid URL to the `HashMap`, so the title will not be displayed in the `JList`.

---

For a proper `URL`, line 78 places the `title` and `URL` into the `HashMap`, and line 79 adds the `title` to the `ArrayList`. Line 87 gets the next title from the HTML document. When the call to `getParameter` at line 87 returns `null`, the loop terminates.

When method `getSitesFromHTMLParameters` returns to `init`, lines 3256 construct the applet's GUI. Line 32 adds the `JLabel` "Choose a site to browse" to the `NORTH` of the `JFrame`'s `BorderLayout`. Line 34 creates `JList` `siteChooser` to allow the user to select a Webpage to view. Lines 3554 register a `ListSelectionListener` to handle the `siteChooser`'s events. Line 56 adds `siteChooser` to the `CENTER` of the `JFrame`'s `BorderLayout`.

When the user selects one of the Web sites listed in `siteChooser`, the program calls method `valueChanged` (lines 3952). Line 42 obtains the selected site name from the `JList`. Line 45 passes the selected site name (the `key`) to `HashMap` method `get`, which locates and returns a reference to the corresponding `URL` object (the `value`) that is assigned to reference `newDocument`.

Line 48 uses `Applet` method `getAppletContext` to get a reference to an `AppletContext` object that represents the applet container. Line 51 uses the `AppletContext` reference `browser` to invoke method `showDocument`, which receives a `URL` object as an argument and passes it to the `AppletContext` (i.e., the browser). The browser displays in the current browser window the World Wide Web resource associated with that `URL`. In this example, all the resources are HTML documents.

For programmers familiar with `HTML frames`, there is a second version of `AppletContext` method `showDocument` that enables an applet to specify the so-called `target frame` in which to display the Web resource. This second version takes two arguments: a `URL` object specifying the resource to display and a string representing the target frame. There are some special target frames that can be used as the second argument. The target frame `_blank` results in a new Web browser window to display the content from the specified URL. The target frame `_self` specifies that the content from the specified URL should be displayed in the same frame as the applet (the applet's HTML page is replaced in this case). The target frame `_top` specifies that the browser should remove the current frames in the browser window, then display the content from the specified URL in the current window. [Note: If you are interested in learning more about HTML, the CD that accompanies this book contains three chapters from our book *Internet and World Wide Web How to Program, Third Edition* that introduce the current version of HTML (known as XHTML) and the Web page formatting capability known as Cascading Style Sheets (CSS).]

## Error-Prevention Tip 24.1

*The applet in [Fig. 24.2](#) must be run from a Web browser, such as Mozilla or Microsoft Internet Explorer, to see the results of displaying another Web page. The `appletviewer` is capable only of executing applets; it ignores all other HTML tags. If the Web sites in the program contained Java applets, only those applets would appear in the `appletviewer` when the user selected a Web site. Each applet would execute in a separate `appletviewer` window.*

## 24.3. Reading a File on a Web Server

Our next example once again hides the networking details from us. The application in [Fig. 24.3](#) uses Swing GUI component `JEditorPane` (from package `javax.swing`) to display the contents of a file on a Web server. The user inputs a URL in the `JTextField` at the top of the window, and the application displays the corresponding document (if it exists) in the `JEditorPane`. Class `JEditorPane` is able to render both plain text and HTML-formatted text, as illustrated in the two screen captures ([Fig. 24.4](#)), so this application acts as a simple Web browser. The application also demonstrates how to process `HyperlinkEvents` when the user clicks a hyperlink in the HTML document. The techniques shown in this example can also be used in applets. However, an applet is allowed to read files only on the server from which it was downloaded.

Figure 24.3. Reading a file by opening a connection through a URL.

(This item is displayed on pages 1114 - 1115 in the print version)

```
1 // Fig. 24.3: ReadServerFile.java
2 // Use a JEditorPane to display the contents of a file on a Web server.
3 import java.awt.BorderLayout;
4 import java.awt.event.ActionEvent;
5 import java.awt.event.ActionListener;
6 import java.io.IOException;
7 import javax.swing.JEditorPane;
8 import javax.swing.JFrame;
9 import javax.swing.JOptionPane;
10 import javax.swing.JScrollPane;
11 import javax.swing.JTextField;
12 import javax.swing.event.HyperlinkEvent;
13 import javax.swing.event.HyperlinkListener;
14
15 public class ReadServerFile extends JFrame
16 {
17 private JTextField enterField; // JTextField to enter site name
18 private JEditorPane contentsArea; // to display Web site
19
20 // set up GUI
21 public ReadServerFile()
22 {
23 super("Simple Web Browser");
24
25 // create enterField and register its listener
26 enterField = new JTextField("Enter file URL here");
27 enterField.addActionListener(
28 new ActionListener()
29 {
30 // get document specified by user
31 public void actionPerformed(ActionEvent event)
32 {
33 getPage(event.getActionCommand());
34 } // end method actionPerformed
35 } // end inner class
36); // end call to addActionListener
37 }
```

```

38 add(enterField, BorderLayout.NORTH);
39
40 contentsArea = new JEditorPane(); // create contentsArea
41 contentsArea.setEditable(false);
42 contentsArea.addHyperlinkListener(
43 new HyperlinkListener()
44 {
45 // if user clicked hyperlink, go to specified page
46 public void hyperlinkUpdate(HyperlinkEvent event)
47 {
48 if (event.getEventType() ==
49 HyperlinkEvent.EventType.ACTIVATED)
50 getPage(event.getURL().toString());
51 } // end method hyperlinkUpdate
52 } // end inner class
53); // end call to addHyperlinkListener
54
55 add(new JScrollPane(contentsArea), BorderLayout.CENTER);
56 setSize(400, 300); // set size of window
57 setVisible(true); // show window
58 } // end ReadServerFile constructor
59
60 // load document
61 private void getPage(String location)
62 {
63 try // load document and display location
64 {
65 contentsArea.setPage(location); // set the page
66 enterField.setText(location); // set the text
67 } // end try
68 catch (IOException ioException)
69 {
70 JOptionPane.showMessageDialog(this,
71 "Error retrieving specified URL", "Bad URL",
72 JOptionPane.ERROR_MESSAGE);
73 } // end catch
74 } // end method getPage
75 } // end class ReadServerFile

```

Figure 24.4. Test class for **ReadServerFile**.

(This item is displayed on pages 1115 - 1116 in the print version)

```

1 // Fig. 24.4: ReadServerFileTest.java
2 // Create and start a ReadServerFile.
3 import javax.swing.JFrame;
4
5 public class ReadServerFileTest
6 {
7 public static void main(String args[])
8 {
9 ReadServerFile application = new ReadServerFile();
10 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 } // end main
12 } // end class ReadServerFileTest

```

[\[View full size image\]](#)

The application class `ReadServerFile` contains `JTextField enterField`, in which the user enters the URL of the file to read and `JEditorPane contentsArea` to display the contents of the file. When the user presses the *Enter* key in `enterField`, the application calls method `actionPerformed` (lines 31-34). Line 33 uses `ActionEvent` method `getActionCommand` to get the string the user input in the `JTextField` and passes the string to utility method `getPage` (lines 61-74).

Line 65 invokes `JEditorPane` method `setPage` to download the document specified by `location` and display it in the `JEditorPane`. If there is an error downloading the document, method `setPage` throws an `IOException`. Also, if an invalid URL is specified, a `MalformedURLException` (a subclass of `IOException`) occurs. If the document loads successfully, line 66 displays the current location in `enterField`.

Typically, an HTML document contains `hyperlinks` text, images or GUI components which, when clicked, provide quick access to another document on the Web. If a `JEditorPane` contains an HTML document and the user clicks a hyperlink, the `JEditorPane` generates a `HyperlinkEvent` (package `javax.swing.event`) and notifies all registered `HyperlinkListeners` (package `javax.swing.event`) of that event. Lines 4253 register a `HyperlinkListener` to handle `HyperlinkEvents`. When a `HyperlinkEvent` occurs, the program calls method `hyperlinkUpdate` (lines 4651). Lines 4849 use `HyperlinkEvent` method `getEventType` to determine the type of the `HyperlinkEvent`. Class `HyperlinkEvent` contains a `public` nested class called `EventType` that declares three `static EventType` objects, which represent the hyperlink event types. `ACTIVATED` indicates that the user clicked a hyperlink to change Web pages, `ENTERED` indicates that the user moved the mouse over a hyperlink and `EXITED` indicates that the user moved the mouse away from a hyperlink. If a hyperlink was `ACTIVATED`, line 50 uses `HyperlinkEvent` method `getURL` to obtain the `URL` represented by the hyperlink. Method `toString` converts the returned `URL` to a string that can be passed to utility method `getThePage`.

## Look-and-Feel Observation 24.1

*A `JEditorPane` generates `HyperlinkEvents` only if it is uneditable.*

## 24.4. Establishing a Simple Server Using Stream Sockets

The two examples discussed so far use high-level Java networking capabilities to communicate between applications. In the examples, it was not the Java programmer's responsibility to establish the connection between a client and a server. The first program relied on the Web browser to communicate with a Web server. The second program relied on a `JEditorPane` to perform the connection. This section begins our discussion of creating your own applications that can communicate with one another.

Establishing a simple server in Java requires five steps. *Step 1* is to create a `ServerSocket` object. A call to the `ServerSocket` constructor, such as

```
ServerSocket server = new ServerSocket(portNumber, queueLength);
```

registers an available TCP port number and specifies a maximum number of clients that can wait to connect to the server (i.e., the queue length). The port number is used by clients to locate the server application on the server computer. This is often called the handshake point. If the queue is full, the server refuses client connections. The constructor establishes the port where the server waits for connections from clients a process known as binding the server to the port. Each client will ask to connect to the server on this port. Only one application at a time can be bound to a specific port on the server.

### Software Engineering Observation 24.1

*Port numbers can be between 0 and 65,535. Most operating systems reserve port numbers below 1024 for system services (e.g., e-mail and World Wide Web servers). Generally, these ports should not be specified as connection ports in user programs. In fact, some operating systems require special access privileges to bind to port numbers below 1024.*

Programs manage each client connection with a `Socket` object. In *Step 2*, the server listens indefinitely (or blocks) for an attempt by a client to connect. To listen for a client connection, the program calls `ServerSocket` method `accept`, as in

```
Socket connection = server.accept();
```

which returns a `Socket` when a connection with a client is established. The `Socket` allows the server to interact with the client. The interactions with the client actually occur at a different server port from the handshake point. This allows the port specified in *Step 1* to be used again in a multithreaded server to accept another client connection. We demonstrate this concept in [Section 24.8](#).

*Step 3* is to get the `OutputStream` and `InputStream` objects that enable the server to communicate with the client by sending and receiving bytes. The server sends information to the client via an `OutputStream` and receives information from the client via an `InputStream`. The server invokes method `getOutputStream` on the `Socket` to get a reference to the `Socket`'s `OutputStream` and invokes method `getInputStream` on the

`Socket` to get a reference to the `Socket`'s `InputStream`.

The stream objects can be used to send or receive individual bytes or sequences of bytes with the `OutputStream`'s method `write` and the `InputStream`'s method `read`, respectively. Often it is useful to send or receive values of primitive types (e.g., `int` and `double`) or `Serializable` objects (e.g., `Strings` or other serializable types) rather than sending bytes. In this case, we can use the techniques discussed in [Chapter 14](#) to wrap other stream types (e.g., `ObjectOutputStream` and `ObjectInputStream`) around the `OutputStream` and `InputStream` associated with the `Socket`. For example,

```
ObjectInputStream input =
 new ObjectInputStream(connection.getInputStream());

ObjectOutputStream output =
 new ObjectOutputStream(connection.getOutputStream());
```

The beauty of establishing these relationships is that whatever the server writes to the `ObjectOutputStream` is sent via the `OutputStream` and is available at the client's `InputStream`, and whatever the client writes to its `OutputStream` (with a corresponding `ObjectOutputStream`) is available via the server's `InputStream`. The transmission of the data over the network is seamless and is handled completely by Java.

*Step 4* is the *processing* phase, in which the server and the client communicate via the `OutputStream` and `InputStream` objects. In *Step 5*, when the transmission is complete, the server closes the connection by invoking the `close` method on the streams and on the `Socket`.

## Software Engineering Observation 24.2

*With sockets, network I/O appears to Java programs to be similar to sequential file I/O. Sockets hide much of the complexity of network programming from the programmer.*

## Software Engineering Observation 24.3

*With Java's multithreading, we can create multithreaded servers that can manage many simultaneous connections with many clients. This multithreaded-server architecture is precisely what popular network servers use.*

## Software Engineering Observation 24.4

*A multithreaded server can take the `Socket` returned by each call to `accept` and create a new thread that manages network I/O across that `Socket`. Alternatively, a multithreaded server can maintain a pool of threads (a set of already existing threads) ready to manage network I/O across the new `Sockets` as they are created. See [Chapter 23](#) for more information on multithreading.*

---

[Page 1119]

## Performance Tip 24.2

*In high-performance systems in which memory is abundant, a multithreaded server can be implemented to create a pool of threads that can be assigned quickly to handle network I/O across each new `Socket` as it is created. Thus, when the server receives a connection, it need not incur the overhead of thread creation. When the connection is closed, the thread is returned to the pool for reuse.*

## 24.5. Establishing a Simple Client Using Stream Sockets

Establishing a simple client in Java requires four steps. In *Step 1*, we create a `Socket` to connect to the server. The `Socket` constructor establishes the connection to the server. For example, the statement

```
Socket connection = new Socket(serverAddress, port);
```

uses the `Socket` constructor with two arguments—the server's address (*serverAddress*) and the *port* number. If the connection attempt is successful, this statement returns a `Socket`. A connection attempt that fails throws an instance of a subclass of `IOException`, so many programs simply catch `IOException`. An `UnknownHostException` occurs specifically when the system is unable to resolve the server address specified in the call to the `Socket` constructor to a corresponding IP address.

In *Step 2*, the client uses `Socket` methods `getInputStream` and `getOutputStream` to obtain references to the `Socket`'s `InputStream` and `OutputStream`. As we mentioned in the preceding section, we can use the techniques of [Chapter 14](#) to wrap other stream types around the `InputStream` and `OutputStream` associated with the `Socket`. If the server is sending information in the form of actual types, the client should receive the information in the same format. Thus, if the server sends values with an `ObjectOutputStream`, the client should read those values with an `ObjectInputStream`.

*Step 3* is the processing phase in which the client and the server communicate via the `InputStream` and `OutputStream` objects. In *Step 4*, the client closes the connection when the transmission is complete by invoking the `close` method on the streams and on the `Socket`. The client must determine when the server is finished sending information so that it can call `close` to close the `Socket` connection. For example, the `InputStream` method `read` returns the value 1 when it detects end-of-stream (also called EOFend-of-file). If an `ObjectInputStream` is used to read information from the server, an `EOFException` occurs when the client attempts to read a value from a stream on which end-of-stream is detected.

## 24.6. Client/Server Interaction with Stream Socket Connections

[Figure 24.5](#) and [Fig. 24.7](#) use stream sockets to demonstrate a simple [client/server chat application](#). The server waits for a client connection attempt. When a client connects to the server, the server application sends the client a `String` object (recall that `Strings` are `Serializable` objects) indicating that the connection was successful. Then the client displays the message. The client and server applications each provide textfields that allow the user to type a message and send it to the other application. When the client or the server sends the string `"TERMINATE"`, the connection terminates. Then the server waits for the next client to connect. The declaration of class `Server` appears in [Fig. 24.5](#). The declaration of class `Client` appears in [Fig. 24.7](#). The screen captures showing the execution between the client and the server are shown as part of [Fig. 24.7](#).

191 } // end method run
192 } // end inner class
193); // end call to SwingUtilities.invokeLater
194 } // end method setTextFieldEditable
195 } // end class Server

```

## Server Class

`Server`'s constructor (lines 3055) creates the server's GUI, which contains a `JTextField` and a `JTextArea`. `Server` displays its output in the `JTextArea`. When the `main` method (lines 712 of [Fig. 24.6](#)) executes, it creates a `Server` object, specifies the window's default close operation and calls method `runServer` (declared at lines 5887).

Figure 24.6. Test class for `Server`.

```

1 // Fig. 24.6: ServerTest.java
2 // Test the Server application.
3 import javax.swing.JFrame;
4
5 public class ServerTest
6 {
7 public static void main(String args[])
8 {
9 Server application = new Server(); // create server
10 application.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
11 application.runServer(); // run server application
12 } // end main
13 } // end class ServerTest

```

[Page 1123]

Method `runServer` sets up the server to receive a connection and processes one connection at a time. Line 62 creates a `ServerSocket` called `server` to wait for connections. The `ServerSocket` listens for a connection from a client at port 12345. The second argument to the constructor is the number of connections that can wait in a queue to connect to the server (100 in this example). If the queue is full when a client attempts to connect, the server refuses the connection.

[Page 1124]

## Common Programming Error 24.1

*Specifying a port that is already in use or specifying an invalid port number when creating a `ServerSocket` results in a `BindException`.*

Line 68 calls method `waitForConnection` (declared at lines 9096) to wait for a client connection. After the connection is established, line 69 calls method `getStreams` (declared at lines 99109) to obtain references to the streams for the connection. Line 70 calls method `processConnection` (declared at lines 112133) to send the initial connection message to the client and to process all messages received from the client. The `finally` block (lines 7680) terminates the client connection by calling method `closeConnection` (lines 136151) even if an exception occurs. Method `displayMessage` (lines 169180) is called from these methods to use the event-dispatch thread to display messages in the application's `JTextArea`.

In method `waitForConnection` (lines 9096), line 93 uses `ServerSocket` method `accept` to wait for a connection from a client. When a connection occurs, the resulting `Socket` is assigned to `connection`. Method `accept` blocks until a connection is received (i.e., the thread in which `accept` is called stops executing until a client connects). Lines 9495 output the host name of the computer that made the connection. `Socket` method `getInetAddress` returns an `InetAddress` (package `java.net`) containing information about the client computer. `InetAddress` method `getHostName` returns the host name of the client computer. For example, there is a special IP address (127.0.0.1) and host name (`localhost`) that is useful for testing networking applications on your local computer (this is also known as the `loopback address`). If `getHostName` is called on an `InetAddress` containing 127.0.0.1, the corresponding host name returned by the method would be `localhost`.

Method `getStreams` (lines 99109) obtains references to the `Socket`'s streams and uses them to initialize an

`ObjectOutputStream` (line 102) and an `ObjectInputStream` (line 106), respectively. Note the call to `ObjectOutputStream` method `flush` at line 103. This statement causes the `ObjectOutputStream` on the server to send a **stream header** to the corresponding client's `ObjectInputStream`. The stream header contains such information as the version of object serialization being used to send objects. This information is required by the `ObjectInputStream` so that it can prepare to receive those objects correctly.

---

[Page 1125]

## Software Engineering Observation 24.5

*When using an `ObjectOutputStream` and `ObjectInputStream` to send and receive data over a network connection, always create the `ObjectOutputStream` first and `flush` the stream so that the client's `ObjectInputStream` can prepare to receive the data. This is required only for networking applications that communicate using `ObjectOutputStream` and `ObjectInputStream`.*

## Performance Tip 24.3

*A computer's input and output components are typically much slower than its memory. Output buffers typically are used to increase the efficiency of an application by sending larger amounts of data fewer times, thus reducing the number of times an application accesses the computer's input and output components.*

Line 114 of method `processConnection` (lines 112-133) calls method `sendData` to send "`SERVER>>> Connection successful`" as a string to the client. The loop at lines 120-132 executes until the server receives the message "`CLIENT>>> TERMINATE`". Line 124 uses `ObjectInputStream` method `readObject` to read a `String` from the client. Line 125 invokes method `displayMessage` to append the message to the `JTextArea`.

When the transmission is complete, method `processConnection` returns, and the program calls method `closeConnection` (lines 136-151) to close the streams associated with the `Socket` and close the `Socket`. Then the server waits for the next connection attempt from a client by continuing with line 68 at the beginning of the `while` loop.

When the user of the server application enters a string in the textfield and presses the `Enter` key, the program calls method `actionPerformed` (lines 40-44), which reads the string from the textfield and calls utility method `sendData` (lines 154-166) to send the string to the client. Method `sendData` writes the object, flushes the output buffer and appends the same string to the text area in the server window. It is not necessary to invoke `displayMessage` to modify the text area here, because method `sendData` is called from an event handler thus, `sendData` executes as part of the event-dispatch thread.

Note that `Server` receives a connection, processes it, closes it and waits for the next connection. A more likely scenario would be a `Server` that receives a connection, sets it up to be processed as a separate thread of execution, then immediately waits for new connections. The separate threads that process existing connections can continue to execute while the `Server` concentrates on new connection requests. This makes the server more efficient, because multiple client requests can be processed concurrently. We demonstrate a multithreaded server in [Section 24.8](#).

## Client Class

Like class `Server`, class `Client`'s ([Fig. 24.7](#)) constructor (lines 2956) creates the GUI of the application (a `JTextField` and a `JTextArea`). `Client` displays its output in the text area. When method `main` (lines 719 of [Fig. 24.8](#)) executes, it creates an instance of class `Client`, specifies the window's default close operation and calls method `runClient` (declared at lines 5979). In this example, you can execute the client from any computer on the Internet and specify the IP address or host name of the server computer as a commandline argument to the program. For example, the command

---

[Page 1126]

```
java Client 192.168.1.15
```

attempts to connect to the `Server` on the computer with IP address `192.168.1.15`.

Figure 24.7. Client portion of a stream-socket connection between client and server.

(This item is displayed on pages 1126 - 1129 in the print version)

[\[View full size image\]](#)

`Client` method `runClient` (lines 5979) sets up the connection to the server, processes messages received from the server and closes the connection when communication is complete. Line 63 calls method `connectToServer` (declared at lines 8292) to perform the connection. After connecting, line 64 calls method `getStreams` (declared at lines 95105) to obtain references to the `Socket`'s stream objects. Then line 65 calls method `processConnection` (declared at lines 108126) to receive and display messages sent from the server. The `finally` block (lines 7578) calls `closeConnection` (lines 129144) to close the streams and the `Socket` even if an exception has occurred. Method `displayMessage` (lines 162173) is called from these methods to use the event-dispatch thread to display messages in the application's textarea.

Method `connectToServer` (lines 8292) creates a `Socket` called `client` (line 87) to establish a connection. The method passes two arguments to the `Socket` constructor the IP address of the server computer and the port number (12345) where the server application is awaiting client connections. In the first argument, `InetAddress` static method `getByName` returns an `InetAddress` object containing the IP address specified as a command-line argument to the application (or `127.0.0.1` if no command-line arguments are specified). Method `getByName` can receive a string containing either the actual IP address or the host name of the

server. The first argument also could have been written other ways. For the localhost address 127.0.0.1, the first argument could be

```
InetAddress.getByName("localhost")
```

or

```
InetAddress. getLocalHost()
```

Also, there are versions of the `Socket` constructor that receive a string for the IP address or host name. The first argument could have been specified as "127.0.0.1" or "localhost". We chose to demonstrate the client/server relationship by connecting between applications executing on the same computer (localhost). Normally, this first argument would be the IP address of another computer. The `InetAddress` object for another computer can be obtained by specifying the computer's IP address or host name as the argument to `InetAddress` method `getByName`. The `Socket` constructor's second argument is the server port number. This must match the port number at which the server is waiting for connections (called the handshake point). Once the connection is made, lines 9091 display a message in the text area indicating the name of the server computer to which the client has connected.

The `Client` uses an `ObjectOutputStream` to send data to the server and an `ObjectInputStream` to receive data from the server. Method `getStreams` (lines 95105) creates the `ObjectOutputStream` and `ObjectInputStream` objects that use the streams associated with the `client` socket.

---

[Page 1131]

Method `processConnection` (lines 108126) contains a loop that executes until the client receives the message "SERVER>>> TERMINATE". Line 117 reads a `String` object from the server. Line 118 invokes `displayMessage` to append the message to the text area.

When the transmission is complete, method `closeConnection` (lines 129144) closes the streams and the `Socket`.

When the user of the client application enters a string in the textfield and presses the *Enter* key, the program calls method `actionPerformed` (lines 4145) to read the string and invoke utility method `sendData` (147159) to send the string to the server. Method `sendData` writes the object, flushes the output buffer and appends the same string to the `JTextArea` in the client window. Once again, it is not necessary to invoke utility method `displayMessage` to modify the text area here, because method `sendData` is called from an event handler.

---

[Page 1132]

## 24.7. Connectionless Client/Server Interaction with Datagrams

We have been discussing connection-oriented, streams-based transmission. Now we consider [connectionless transmission with datagrams](#).

Connection-oriented transmission is like the telephone system in which you dial and are given a connection to the telephone of the person with whom you wish to communicate. The connection is maintained for the duration of your phone call, even when you are not talking.

Connectionless transmission with datagrams is more like the way mail is carried via the postal service. If a large message will not fit in one envelope, you break it into separate message pieces that you place in separate, sequentially numbered envelopes. Each of the letters is then mailed at the same time. The letters could arrive in order, out of order or not at all (the last case is rare, but it does happen). The person at the receiving end reassembles the message pieces into sequential order before attempting to make sense of the message. If your message is small enough to fit in one envelope, you need not worry about the "out-of-sequence" problem, but it is still possible that your message might not arrive. One difference between datagrams and postal mail is that duplicates of datagrams can arrive at the receiving computer.

[Figure 24.9](#)[Fig. 24.12](#) use datagrams to send packets of information via the User Datagram Protocol (UDP) between a client application and a server application. In the [Client](#) application ([Fig. 24.11](#)), the user types a message into a textfield and presses *Enter*. The program converts the message into a [byte](#) array and places it in a datagram packet that is sent to the server. The [Server](#) ([Fig. 24.9](#)) receives the packet and displays the information in it, then [echoes](#) the packet back to the client. Upon receiving the packet, the client displays the information it contains.

**Client** window after sending packet to **Server** and receiving packet back from **Server**

## Server Class

Class `Server` (Fig. 24.9) declares two `DatagramPackets` that the server uses to send and receive information and one `DatagramSocket` that sends and receives the packets. The `Server` constructor (lines 1937) creates the graphical user interface in which the packets of information will be displayed. Line 30 creates the `DatagramSocket` in a `TRY` block. Line 30 uses the `DatagramSocket` constructor that takes an integer port number argument (5000 in this example) to bind the server to a port where it can receive packets from clients. `Clients` sending packets to this `Server` specify the same port number in the packets they send. A `SocketException` is thrown if the `DatagramSocket` constructor fails to bind the `DatagramSocket` to the specified port.

---

[Page 1138]

### Common Programming Error 24.2

*Specifying a port that is already in use or specifying an invalid port number when creating a `DatagramSocket` results in a `SocketException`.*

`Server` method `waitForPackets` (lines 4068) uses an infinite loop to wait for packets to arrive at the `Server`. Lines 4748 create a `DatagramPacket` in which a received packet of information can be stored. The `DatagramPacket` constructor for this purpose receives two arguments: a `byte` array in which the data will be stored and the length of the array. Line 50 uses `DatagramSocket` method `receive` to wait for a packet to arrive at the `Server`. Method `receive` blocks until a packet arrives, then stores the packet in its `DatagramPacket` argument. The method throws an `IOException` if an error occurs while receiving a packet.

When a packet arrives, lines 5358 call method `displayMessage` (declared at lines 8697) to append the packet's contents to the text area. `DatagramPacket` method `getAddress` (line 54) returns an `InetAddress` object containing the host name of the computer from which the packet was sent. Method `getPort` (line 55) returns an integer specifying the port number through which the host computer sent the packet. Method `getLength` (line 56) returns an integer representing the number of bytes of data sent. Method `getData` (line 57) returns a `byte` array containing the data. Lines 5758 initialize a `String` object using a three-argument constructor that takes a `byte` array, the offset and the length. This `String` is then appended to the text to

display.

After displaying a packet, line 60 calls method `sendPacketToClient` (declared at lines 7183) to create a new packet and send it to the client. Lines 7779 create a `DatagramPacket` and pass four arguments to its constructor. The first argument specifies the `byte` array to send. The second argument specifies the number of bytes to send. The third argument specifies the client computer's Internet address, to which the packet will be sent. The fourth argument specifies the port where the client is waiting to receive packets. Line 81 sends the packet over the network. Method `send` of `DatagramSocket` throws an `IOException` if an error occurs while sending a packet.

---

[Page 1139]

## Client Class

Class `Client` (Fig. 24.11) works similarly to class `Server`, except that the `Client` sends packets only when the user types a message in a textfield and presses the *Enter* key. When this occurs, the program calls method `actionPerformed` (lines 3257), which converts the string the user entered into a `byte` array (line 41). Lines 4445 create a `DatagramPacket` and initialize it with the `byte` array, the length of the string that was entered by the user, the IP address to which the packet is to be sent (`InetAddress.getLocalHost()` in this example) and the port number at which the `Server` is waiting for packets (5000 in this example). Line 47 sends the packet. Note that the client in this example must know that the server is receiving packets at port 5000 otherwise, the server will not receive the packets.

Note that the `DatagramSocket` constructor call (line 71) in this application does not specify any arguments. This no-argument constructor allows the computer to select the next available port number for the `DatagramSocket`. The client does not need a specific port number, because the server receives the client's port number as part of each `DatagramPacket` sent by the client. Thus, the server can send packets back to the same computer and port number from which it receives a packet of information.

`Client` method `waitForPackets` (lines 81107) uses an infinite loop to wait for packets from the server. Line 91 blocks until a packet arrives. This does not prevent the user from sending a packet, because the GUI events are handled in the event-dispatch thread. It only prevents the `while` loop from continuing until a packet arrives at the `Client`. When a packet arrives, line 91 stores it in `receivePacket`, and lines 9499 call method `displayMessage` (declared at lines 110121) to display the packet's contents in the textarea.

## 24.8. Client/Server Tic-Tac-Toe Using a Multithreaded Server

In this section, we present the popular game Tic-Tac-Toe implemented by using client/server techniques with stream sockets. The program consists of a `TicTacToeServer` application ([Fig. 24.13](#)[Fig. 24.14](#)) that allows two `TicTacToeClient` applications ([Fig. 24.15](#)[Fig. 24.16](#)) to connect to the server and play Tic-Tac-Toe. Sample outputs are shown in [Fig. 24.17](#).

Figure 24.13. Server side of client/server Tic-Tac-Toe program.

(This item is displayed on pages 1140 - 1145 in the print version)

## TicTacToeServer Class

As the `TicTacToeServer` receives each client connection, it creates an instance of inner-class `Player` (lines 182301 of [Fig. 24.13](#)) to process the client in a separate thread. These threads enable the clients to play the game independently. The first client to connect to the server is player X and the second is player O. Player X makes the first move. The server maintains the information about the board so it can determine whether a player's move is valid or invalid.

We begin with a discussion of the server side of the Tic-Tac-Toe game. When the `TicTacToeServer` application executes, the `main` method (lines 712 of [Fig. 24.14](#)) creates a `TicTacToeServer` object called `application`. The constructor (lines 3469 of [Fig. 24.13](#)) attempts to set up a `ServerSocket`. If successful, the program displays the server window, then `main` invokes the `TicTacToeServer` method `execute` (lines 72100). Method `execute` loops twice, blocking at line 79 each time while waiting for a client connection. When a client connects, line 79 creates a new `Player` object to manage the connection as a separate thread, and line 80 executes the `Player` in the `runGame` thread pool.

---

When the `TicTacToeServer` creates a `Player`, the `Player` constructor (lines 192208) receives the `Socket` object representing the connection to the client and gets the associated input and output streams. Line 201 creates a `Formatter` (see [Chapter 28](#)) by wrapping it around the output stream of the socket. The `Player`'s `run` method (lines 219297) controls the information that is sent to and received from the client. First, it passes to the client the character that the client will place on the board when a move is made (line 225). Line 226 calls `Formatter` method `flush` to force this output to the client. Line 241 suspends player X's thread as it starts executing, because player X can move only after player O connects.

After player O connects, the game can be played, and the `run` method begins executing its `while` statement (lines 264283). Each iteration of this loop reads an integer (line 269) representing the location where the client wants to place a mark, and line 272 invokes the `TicTacToeServer` method `validateAndMove` (declared at lines 118163) to check the move. If the move is valid, line 275 sends a message to the client to this effect. If not, line 280 sends a message indicating that the move was invalid. The program maintains board locations as numbers from 0 to 8 (0 through 2 for the first row, 3 through 5 for the second row and 6 through 8 for the third row).

---

Method `validateAndMove` (lines 118163 in class `TicTacToeServer`) allows only one player at a time to move, thereby preventing them from modifying the state information of the game simultaneously. If the `Player` attempting to validate a move is not the current player (i.e., the one allowed to make a move), it is placed in a `wait` state until its turn to move. If the position for the move being validated is already occupied on the board, `validMove` returns `false`. Otherwise, the server places a mark for the player in its local representation of the board (line 142), notifies the other `Player` object (line 146) that a move has been made (so that the client can be sent a message), invokes method `signal` (line 152) so that the waiting `Player` (if there is one) can validate a move and returns `true` (line 159) to indicate that the move is valid.

## **TicTacToeClient Class**

Each `TicTacToeClient` application ([Fig. 24.15](#)) maintains its own GUI version of the Tic-Tac-Toe board on which it displays the state of the game. The clients can place a mark only in an empty square on the board. Inner class `Square` (lines 205262 of [Fig. 24.15](#)) implements each of the nine squares on the board. When a `TicTacToeClient` begins execution, it creates a `JTextArea` in which messages from the server and a representation of the board using nine `Square` objects are displayed. The `startClient` method (lines 80100) opens a connection to the server and gets the associated input and output streams from the `Socket` object. Lines 8586 make a connection to the server. Class `TicTacToeClient` implements interface `Runnable` so that a separate thread can read messages from the server. This approach enables the user to interact with the board (in the event-dispatch thread) while waiting for messages from the server. After establishing the connection to the server, line 99 executes the client with the `worker ExecutorService`. The `run` method (lines 103124) controls the separate thread of execution. The method first reads the mark character (X or O) from the server (line 105), then loops continuously (lines 121125) and reads messages from the server (line 124). Each message is passed to the `processMessage` method (lines 129156) for processing.

---

If the message received is "Valid move.", lines 134-135 display the message "Valid move, please wait." and call method `setMark` (lines 173-184) to set the client's mark in the current square (the one in which the user clicked) using `SwingUtilities` method `invokeLater` to ensure that the GUI updates occur in the event-dispatch thread. If the message received is "Invalid move, try again.", line 139 displays the message so that the user can click a different square. If the message received is "Opponent moved.", line 145 reads an integer from the server indicating where the opponent moved, and lines 149-150 place a mark in that square of the board (again using `SwingUtilities` method `invokeLater` to ensure that the GUI updates occur in the event-dispatch thread). If any other message is received, line 155 simply displays the message. [Figure 24.17](#) shows sample screen captures of two applications interacting via the `TicTacToeServer`.

## 24.9. Security and the Network

As much as we look forward to writing a great variety of powerful network-based applications, our efforts may be limited because of security concerns. Many Web browsers, such as Mozilla and Microsoft Internet Explorer, by default prohibit Java applets from doing file processing on the machines on which they execute. Think about it. A Java applet is designed to be sent to your browser via an HTML document that could be downloaded from any Web server in the world. Often you will know very little about the sources of Java applets that will execute on your system. To allow these applets free rein with your files could be disastrous.

A more subtle situation occurs with limiting the machines to which executing applets can make network connections. To build truly collaborative applications, we would ideally like to have our applets communicate with machines almost anywhere. The Java security manager in a Web browser often restricts an applet so that it can communicate only with the machine from which it was originally downloaded.

These restrictions may seem too strict. However, the Java Security API now provides capabilities for digitally signed applets that will enable browsers to determine whether an applet is downloaded from a [trusted source](#). A trusted applet can be given additional access to the computer on which it is executing. The features of the Java Security API and additional networking capabilities are discussed in our text *Advanced Java 2 Platform How to Program*.

## 24.10. Case Study: DeitelMessenger Server and Client

Chat rooms have become common on the Internet. They provide a central location where users can chat with each other via short text messages. Each participant can see all messages that the other users post, and each user can post messages. This section presents our capstone networking case study, which integrates many of the Java networking, multithreading and Swing GUI features we have learned thus far to build an online chat system. We also introduce [multicasting](#), which enables an application to send `DatagramPackets` to groups of clients. After reading this section, you will be able to build more significant networking applications.

### 24.10.1. DeitelMessengerServer and Supporting Classes

`DeitelMessengerServer` ([Fig. 24.18](#)) is the heart of the online chat system. This class appears in package `com.deitel.messenger.sockets.server`. Chat clients can participate in a chat by connecting to the `DeitelMessengerServer`. Method `startServer` (lines 2053) launches `DeitelMessengerServer`. Lines 2829 create a `ServerSocket` to accept incoming network connections. Recall that the `ServerSocket` constructor takes as its first argument the port on which the server should listen for incoming connections. Interface `SocketMessengerConstants` ([Fig. 24.20](#)) declares the port number as the constant `SERVER_PORT` to ensure that the server and the clients use the correct port number.

Figure 24.18. `DeitelMessengerServer` for managing a chat room.

(This item is displayed on pages 1155 - 1156 in the print version)

```
1 // Fig. 24.18: DeitelMessengerServer.java
2 // DeitelMessengerServer is a multi-threaded, socket- and
3 // packet-based chat server.
4 package com.deitel.messenger.sockets.server;
5
6 import java.net.ServerSocket;
7 import java.net.Socket;
8 import java.io.IOException;
9 import java.util.concurrent.Executors;
10 import java.util.concurrent.ExecutorService;
11
12 import com.deitel.messenger.MessageListener;
13 import static com.deitel.messenger.sockets.SocketMessengerConstants.*;
14
15 public class DeitelMessengerServer implements MessageListener
16 {
17 private ExecutorService serverExecutor; // executor for server
18
19 // start chat server
20 public void startServer()
21 {
22 // create executor for server runnables
23 serverExecutor = Executors.newCachedThreadPool();
24
25 try // create server and manage new clients
26 {
```

```

27 // create ServerSocket for incoming connections
28 ServerSocket serverSocket =
29 new ServerSocket(SERVER_PORT, 100);
30
31 System.out.printf("%s%d%s", "Server listening on port ",
32 SERVER_PORT, " ...");
33
34 // listen for clients constantly
35 while (true)
36 {
37 // accept new client connection
38 Socket clientSocket = serverSocket.accept();
39
40 // create MessageReceiver for receiving messages from client
41 serverExecutor.execute(
42 new MessageReceiver(this, clientSocket));
43
44 // print connection information
45 System.out.println("Connection received from: " +
46 clientSocket.getInetAddress());
47 } // end while
48 } // end try
49 catch (IOException ioException)
50 {
51 ioException.printStackTrace();
52 } // end catch
53 } // end method startServer
54
55 // when new message is received, broadcast message to clients
56 public void messageReceived(String from, String message)
57 {
58 // create String containing entire message
59 String completeMessage = from + MESSAGE_SEPARATOR + message;
60
61 // create and start MulticastSender to broadcast messages
62 serverExecutor.execute(
63 new MulticastSender(completeMessage.getBytes()));
64 } // end method messageReceived
65 } // end class DeitelMessengerServer

```

Lines 35-47 listen continuously for new client connections. Line 38 invokes `ServerSocket` method `accept` to wait for and accept a new client connection. Lines 41-42 create and start a new `MessageReceiver` for the client. Class `MessageReceiver` (Fig. 24.22) of package `com.deitel.messenger.sockets.server` implements `Runnable` and listens for incoming messages from a client. The first argument to the `MessageReceiver` constructor is a `MessageListener` (Fig. 24.21), to which messages from the client should be delivered. Class `DeitelMessengerServer` implements interface `MessageListener` (line 15) of package `com.deitel.messenger` and therefore can pass the `this` reference to the `MessageReceiver` constructor.

When each `MessageReceiver` receives a new message from a client, the `MessageReceiver` passes the message to a `MessageListener` through method `messageReceived` (lines 56-64). Line 59 concatenates the `from` string with the separator `>>>` and the message body. Lines 62-63 create and start a new `MulticastSender` to deliver `completeMessage` to all clients. Class `MulticastSender` (Fig. 24.23) of package `com.deitel.messenger.sockets.server` uses multicasting as an efficient mechanism for sending one message to multiple clients. We discuss the details of multicasting shortly. Method `main` (lines 711 of Fig. 24.19) creates a new `DeitelMessengerServer` instance and starts the server.

Figure 24.19. Test class for **DeitelMessengerServer**.

```
1 // Fig. 24.19: DeitelMessengerServerTest.java
2 // Test the DeitelMessengerServer class.
3 package com.deitel.messenger.sockets.server;
4
5 public class DeitelMessengerServerTest
6 {
7 public static void main (String args[])
8 {
9 DeitelMessengerServer application = new DeitelMessengerServer();
10 application.startServer(); // start server
11 } // end main
12 } // end class DeitelMessengerServerTest
```

```
Server listening on port 12345 ...
Connection received from: /127.0.0.1
Connection received from: /127.0.0.1
Connection received from: /127.0.0.1
```

Interface **SocketMessengerConstants** (Fig. 24.20) declares constants for use in the various classes that make up the Deitel messenger system. Classes can access these **static** constants by using a **static import** as shown in Fig. 24.22.

Figure 24.20. **SocketMessengerConstants** declares constants for use in the **DeitelMessengerServer** and **DeitelMessenger**.

```
1 // Fig. 24.20: SocketMessengerConstants.java
2 // SocketMessengerConstants defines constants for the port numbers
3 // and multicast address in DeitelMessenger
4 package com.deitel.messenger.sockets;
5
6 public interface SocketMessengerConstants
7 {
8 // address for multicast datagrams
9 public static final String MULTICAST_ADDRESS = "239.0.0.1";
10
11 // port for listening for multicast datagrams
12 public static final int MULTICAST_LISTENING_PORT = 5555;
13
14 // port for sending multicast datagrams
15 public static final int MULTICAST_SENDING_PORT = 5554;
16
17 // port for Socket connections to DeitelMessengerServer
18 public static final int SERVER_PORT = 12345;
19
20 // String that indicates disconnect
```

```

21 public static final String DISCONNECT_STRING = "DISCONNECT";
22
23 // String that separates the user name from the message body
24 public static final String MESSAGE_SEPARATOR = ">>>";
25
26 // message size (in bytes)
27 public static final int MESSAGE_SIZE = 512;
28 } // end interface SocketMessengerConstants

```

[Page 1158]

Line 9 declares the `String` constant `MULTICAST_ADDRESS`, which contains the address to which a `MulticastSender` (Fig. 24.23) should send messages. This address is one of the addresses reserved for multicast, which we describe in the discussion of Fig. 24.23. Line 12 declares the integer constant `MULTICAST_LISTENING_PORT` the port on which clients should listen for new messages. Line 15 declares the integer constant `MULTICAST_SENDING_PORT` the port to which a `MulticastSender` should post new messages at the `MULTICAST_ADDRESS`. Line 18 declares the integer constant `SERVER_PORT` the port on which `DeitelMessengerServer` listens for incoming client connections. Line 21 declares `String` constant `DISCONNECT_STRING`, which is the `String` that a client sends to `DeitelMessengerServer` when the user wishes to leave the chat room. Line 24 declares `String` constant `MESSAGE_SEPARATOR`, which separates the user name from the message body. Line 27 specifies the maximum message size in bytes.

Many different classes in the Deitel messenger system receive messages. For example, `DeitelMessengerServer` receives messages from clients and delivers them to all chat room participants. As we will see, the user interface for each client also receives messages and displays them to the users. Each class that receives messages implements interface `MessageListener` (Fig. 24.21). The interface (from package `com.deitel.messenger`) declares method `messageReceived`, which allows an implementing class to receive chat messages. Method `messageReceived` takes two string arguments representing the name of the sender and the message body, respectively.

Figure 24.21. `MessageListener` interface that declares method `messageReceived` for receiving new chat messages.

```

1 // Fig. 24.21: MessageListener.java
2 // MessageListener is an interface for classes that wish to
3 // receive new chat messages.
4 package com.deitel.messenger;
5
6 public interface MessageListener
7 {
8 // receive new chat message
9 public void messageReceived(String from, String message);
10 } // end interface MessageListener

```

`DeitelMessengerServer` uses instances of class `MessageReceiver` (Fig. 24.22) from package `com.deitel.messenger.sockets.server` to listen for new messages from each client. Class `MessageReceiver` implements interface `Runnable`. This enables `DeitelMessengerServer` to create an object of class `MessageReceiver` to run in a separate thread for each client, so that messages from multiple clients can be handled concurrently. When `DeitelMessengerServer` receives a new client connection, `DeitelMessengerServer` creates a new `MessageReceiver` for the client, then continues listening for new client connections. The `MessageReceiver` listens for messages from a single client and passes them back to the `DeitelMessengerServer` through method `messageReceived`.

Figure 24.22. **MessageReceiver** for listening for new messages from **DeitelMessengerServer** clients in separate threads.

(This item is displayed on pages 1159 - 1161 in the print version)

```

1 // Fig. 24.22: MessageReceiver.java
2 // MessageReceiver is a Runnable that listens for messages from a
3 // particular client and delivers messages to a MessageListener.
4 package com.deitel.messenger.sockets.server;
5
6 import java.io.BufferedReader;
7 import java.io.IOException;
8 import java.io.InputStreamReader;
9 import java.net.Socket;
10 import java.net.SocketTimeoutException;
11 import java.util.StringTokenizer;
12
13 import com.deitel.messenger.MessageListener;
14 import static com.deitel.messenger.sockets.SocketMessengerConstants.*;
15
16 public class MessageReceiver implements Runnable
17 {
18 private BufferedReader input; // input stream
19 private MessageListener messageListener; // message listener
20 private boolean keepListening = true; // when false, ends runnable
21
22 // MessageReceiver constructor
23 public MessageReceiver(MessageListener listener, Socket clientSocket)
24 {
25 // set listener to which new messages should be sent
26 messageListener = listener;
27
28 try
29 {
30 // set timeout for reading from client
31 clientSocket.setSoTimeout(5000); // five seconds
32
33 // create BufferedReader for reading incoming messages
34 input = new BufferedReader(new InputStreamReader(
35 clientSocket.getInputStream()));
36 } // end try
37 catch (IOException ioException)
38 {
39 ioException.printStackTrace();
40 } // end catch
41 } // end MessageReceiver constructor
42
43 // listen for new messages and deliver them to MessageListener
44 public void run()
45 {
46 String message; // String for incoming messages
47
48 // listen for messages until stopped
49 while (keepListening)
50 {
51 try

```

```

52 {
53 message = input.readLine(); // read message from client
54 } // end try
55 catch (SocketTimeoutException socketTimeoutException)
56 {
57 continue; // continue to next iteration to keep listening
58 } // end catch
59 catch (IOException ioException)
60 {
61 ioException.printStackTrace();
62 break;
63 } // end catch
64
65 // ensure non-null message
66 if (message != null)
67 {
68 // tokenize message to retrieve user name and message body
69 StringTokenizer tokenizer = new StringTokenizer(
70 message, MESSAGE_SEPARATOR);
71
72 // ignore messages that do not contain a user
73 // name and message body
74 if (tokenizer.countTokens() == 2)
75 {
76 // send message to MessageListener
77 messageListener.messageReceived(
78 tokenizer.nextToken(), // user name
79 tokenizer.nextToken()); // message body
80 } // end if
81 else
82 {
83 // if disconnect message received, stop listening
84 if (message.equalsIgnoreCase(
85 MESSAGE_SEPARATOR + DISCONNECT_STRING))
86 stopListening();
87 } // end else
88 } // end if
89 } // end while
90
91 try
92 {
93 input.close(); // close BufferedReader (also closes Socket)
94 } // end try
95 catch (IOException ioException)
96 {
97 ioException.printStackTrace();
98 } // end catch
99 } // end method run
100
101 // stop listening for incoming messages
102 public void stopListening()
103 {
104 keepListening = false;
105 } // end method stopListening
106 } // end class MessageReceiver

```

The `MessageReceiver` constructor (lines 2341) takes a `MessageListener` as its first argument. The `MessageReceiver` will deliver new messages to this listener by invoking its `messageReceived` method. The

`MessageReceiver` constructor's `Socket` argument is the connection to a particular client. Line 26 sets the `MessageListener` to which the `MessageReceiver` should deliver new messages. Line 31 invokes `Socket` method `setSoTimeout` with an integer argument of 5000 milliseconds. Reading data from a `Socket` is a **blocking call**the current thread does not execute until the read operation completes. Method `setSoTimeout` specifies that if no data is received in the given number of milliseconds, the `Socket` should issue a `SocketTimeoutException`, which the current thread can catch, then continue executing. This technique prevents the current thread from dead-locking if no more data is available from the `Socket`. Lines 34-35 create a new `BufferedReader` for the `clientSocket`'s `InputStream`. The `MessageReceiver` uses this `BufferedReader` to read new messages from the client.

Method `run` (lines 44-99) listens continuously for new messages from the client. Lines 49-99 loop as long as the `boolean` variable `keepListening` is `TRUE`. Line 53 invokes `BufferedReader` method `readLine` to read a line of text from the client. If more than 5000 milliseconds pass without any data being read, method `readLine` throws an `InterruptedException`, which indicates that the time-out set on line 31 has expired. Line 57 uses a `continue` statement to go to the next iteration of the `while` loop to continue listening for messages. Lines 59-63 catch an `IOException`, which indicates a more severe problem from method `readLine`. In this case, line 61 prints a stack trace to aid in debugging the application, and line 62 uses keyword `break` to terminate the loop.

When sending a message to the server, the client separates the user's name from the message body with `MESSAGE_SEPARATOR` declared in interface `SocketMessengerConstants`. If no exceptions are thrown when reading data from the client and the message is not null (line 66), lines 69-70 create a new `StringTokenizer` that uses delimiter `MESSAGE_SEPARATOR` to separate each message into two tokens: the sender's user name and the message. Line 74 checks for the proper number of tokens (using `StringTokenizer` method `countTokens`), and lines 77-79 invoke method `messageReceived` of interface `MessageListener` to deliver the new message to the registered `MessageListener`. If the `StringTokenizer` does not produce two tokens, lines 84-85 check the message to see whether it matches the constant `DISCONNECT_STRING`, which would indicate that the user wishes to leave the chat room. Line 84 uses `String` method `equalsIgnoreCase` to test whether the input `String` equals the disconnect string. This method is equivalent to `String` method `equals`, but it does not consider the case of the letters. This allows the user to type `DISCONNECT`, `disconnect` or even `dIsCoNNEcT` to terminate the connection. If the strings match, line 86 invokes `MessageReceiver` method `stopListening` to terminate the `MessageReceiver`.

---

[Page 1162]

Method `stopListening` (lines 102-105) sets `boolean` variable `keepListening` to `false`. This causes the `while` loop condition that starts at line 49 to fail and causes the `MessageReceiver` to close the client `Socket` (line 93). Then method `run` returns, which terminates the `MessageReceiver`'s execution.

`MulticastSender` (Fig. 24.23) delivers `DatagramPackets` containing chat messages to a group of clients. Multicast is an efficient way to send data to many clients without the overhead of broadcasting it to every host on the Internet. To understand multicast, let us look at a real-world analogy: the relationship between a magazine's publisher and its subscribers. The publisher produces a magazine and provides it to a distributor. Customers obtain a subscription and begin receiving the magazine in the mail from the distributor. This communication is quite different from a television broadcast. When a television station produces a television show, the station broadcasts the show throughout a geographical region or perhaps throughout the world by using satellites. Broadcasting a show for 1,000,000 viewers costs no more than broadcasting one for 100 viewers: the signal carrying the broadcast reaches a wide area. However, printing and delivering a magazine to 1,000,000 readers would be much more expensive than for 100 readers. Most publishers could not stay in business if they had to broadcast their magazines to everyone, so they multicast them to a group of subscribers instead.

Figure 24.23. `MulticastSender` for delivering outgoing messages to a multicast group via `DatagramPackets`.

(This item is displayed on pages 1162 - 1163 in the print version)

```

1 // Fig. 24.23: MulticastSender.java
2 // MulticastSender broadcasts a chat message using a multicast datagram.
3 package com.deitel.messenger.sockets.server;
4
5 import java.io.IOException;
6 import java.net.DatagramPacket;
7 import java.net.DatagramSocket;
8 import java.net.InetAddress;
9
10 import static com.deitel.messenger.sockets.SocketMessengerConstants.*;
11
12 public class MulticastSender implements Runnable
13 {
14 private byte[] messageBytes; // message data
15
16 public MulticastSender(byte[] bytes)
17 {
18 messageBytes = bytes; // create the message
19 } // end MulticastSender constructor
20
21 // deliver message to MULTICAST_ADDRESS over DatagramSocket
22 public void run()
23 {
24 try // deliver message
25 {
26 // create DatagramSocket for sending message
27 DatagramSocket socket =
28 new DatagramSocket(MULTICAST_SENDING_PORT);
29
30 // use InetAddress reserved for multicast group
31 InetAddress group = InetAddress.getByName(MULTICAST_ADDRESS);
32
33 // create DatagramPacket containing message
34 DatagramPacket packet = new DatagramPacket(messageBytes,
35 messageBytes.length, group, MULTICAST_LISTENING_PORT);
36
37 socket.send(packet); // send packet to multicast group
38 socket.close(); // close socket
39 } // end try
40 catch (IOException ioException)
41 {
42 ioException.printStackTrace();
43 } // end catch
44 } // end method run
45 } // end class MulticastSender

```

Using multicast, an application can "publish" `DatagramPackets` to "subscriber" applications by sending them to a [multicast address](#), which is an IP address reserved for multicast. Multicast addresses are in the range from 224.0.0.0 to 239.255.255.255. Addresses starting with 239 are reserved for intranets, so we use one of these (239.0.0.1) in our case study. Clients that wish to receive these `DatagramPackets` can connect to the appropriate multicast address to join the group of subscribers the [multicast group](#). When an application sends a `DatagramPacket` to the multicast address, each client in the group receives it. Multicast `DatagramPackets`, like unicast `DatagramPackets` ([Fig. 24.7](#)), are not reliable packets are not guaranteed to reach any destination or arrive in any particular order.

Class `MulticastSender` implements interface `Runnable` to enable `DeitelMessengerServer` to send multicast messages in a separate thread. The `DeitelMessengerServer` creates a `MulticastSender` with the contents of the message and starts the thread. The `MulticastSender` constructor (lines 1619) takes as an argument an array of `byte`s containing the message.

Method `run` (lines 2244) delivers the message to the multicast address. Lines 2728 create a new `DatagramSocket`. Recall from [Section 24.7](#) that we use `DatagramSocket`s to send `unicast` `DatagramPacket`s packets sent from one host directly to another host. Multicast `DatagramPackets` are sent the same way, except that the address to which they are sent is a multicast address. Line 31 create an `InetAddress` object for the multicast address, which is declared as a constant in interface `SocketMessengerConstants`. Lines 3435 create the `DatagramPacket` containing the message. The first argument to the `DatagramPacket` constructor is the `byte` array containing the message. The second argument is the length of the `byte` array. The third argument specifies the `InetAddress` to which the packet should be sent, and the last specifies the port number at which the packet should be delivered to the multicast address. Line 37 sends the packet with `DatagramSocket` method `send`. All clients listening to the multicast address on the proper port will receive this `DatagramPacket`. Line 38 closes the `DatagramSocket`, and the `run` method returns, terminating the `MulticastSender`.

---

[Page 1164]

## Executing the `DeitelMessengerServerTest`

To execute the `DeitelMessengerServerTest`, open a **Command Prompt** window and change directories to the location in which package `com.deitel.messenger.sockets.server` resides (i.e., the directory in which `com` is located). Then type

```
java com.deitel.messenger.sockets.server.DeitelMessengerServerTest
```

to execute the server.

## 24.10.2. DeitelMessenger Client and Supporting Classes

The client for the `DeitelMessengerServer` has several components. A class that implements interface `MessageManager` ([Fig. 24.24](#)) manages communication with the server. A `Runnable` subclass listens for messages at `DeitelMessengerServer`'s multicast address. Another `Runnable` subclass sends messages from the client to the server. A `JFrame` subclass provides the client's GUI.

Figure 24.24. `MessageManager` interface that declares methods for communicating with a `DeitelMessengerServer`.

```

1 // Fig. 24.24: MessageManager.java
2 // MessageManger is an interface for objects capable of managing
3 // communications with a message server.
4 package com.deitel.messenger;
5
6 public interface MessageManager
7 {
8 // connect to message server and route incoming messages
9 // to given MessageListener
10 public void connect(MessageListener listener);
11
12 // disconnect from message server and stop routing
13 // incoming messages to given MessageListener
14 public void disconnect(MessageListener listener);
15
16 // send message to message server
17 public void sendMessage(String from, String message);
18 } // end interface MessageManager

```

Interface `MessageManager` (Fig. 24.24) declares methods for managing communication with `DeitelMessengerServer`. We declare this interface to abstract the base functionality a client needs to interact with a chat server from the underlying communication mechanism. This abstraction enables us to provide `MessageManager` implementations that use other network protocols to implement the communication details. For example, if we wanted to connect to a different chat server that did not use multicast `DatagramPacketS`, we could implement the `MessageManager` interface with the appropriate network protocols for this alternative messaging server. We would not need to modify any other code in the client, because the client's other components refer only to interface `MessageManager`, not a particular `MessageManager` implementation. Similarly, `MessageManager` methods refer to other components of the client only through interface `MessageListener`, so other client components can change without requiring changes in the `MessageManager` or its implementations. Method `connect` (line 10) connects a `MessageManager` to `DeitelMessengerServer` and routes incoming messages to the appropriate `MessageListener`. Method `disconnect` (line 14) disconnects a `MessageManager` from the `DeitelMessengerServer` and stops delivering messages to the given `MessageListener`. Method `sendMessage` (line 17) sends a new message to `DeitelMessengerServer`.

---

[Page 1165]

Class `SocketMessageManager` (Fig. 24.25) implements `MessageManager` (line 18), using `Sockets` and `MulticastSocketS` to communicate with `DeitelMessengerServer` and receive incoming messages. Line 20 declares the `Socket` used to connect to and send messages to `DeitelMessengerServer`. Line 22 declares a `PacketReceiver` (Fig. 24.27) that listens for new incoming messages. The `connected` flag (line 23) indicates whether the `SocketMessageManager` is currently connected to `DeitelMessengerServer`.

---

[Page 1167]

Figure 24.25. `SocketMessageManager` implementation of interface `MessageManager` for communicating via `Sockets` and multicast `DatagramPackets`.

93 serverExecutor.execute(
94 new MessageSender(clientSocket, from, message));
95 } // end method sendMessage
96 } // end method SocketMessageManager

```

The `SocketMessageManager` constructor (lines 2630) receives the address of the `DeitelMessengerServer` to which `SocketMessageManager` should connect. Method `connect` (lines 3352) connects `SocketMessageManager` to `DeitelMessengerServer`. If it was connected previously, line 36 returns from method `connect`. Lines 4041 create a new `Socket` to communicate with the server. Line 41 creates an `InetAddress` object for the server's address and uses the constant `SERVER_PORT` to specify the `port` on which the client should connect. Line 44 creates a new `PacketReceiver`, which listens for incoming multicast messages from the server, and line 45 executes the `Runnable`. Line 46 updates `boolean` variable `connected` to indicate that `SocketMessageManager` is connected to the server.

Method `disconnect` (lines 5584) terminates the `SocketMessageManager`'s connection to the server. If `SocketMessageManager` is not connected, line 58 returns from method `disconnect`. Lines 6364 create a new `MessageSender` (Fig. 24.26) to send `DISCONNECT_STRING` to `DeitelMessengerServer`. Class `MessageSender` delivers a message to `DeitelMessengerServer` over the `SocketMessageManager`'s `Socket` connection. Line 65 starts the `MessageSender` to deliver the message using method `submit` of the `ExecutorService`. This method returns a `Future` which represents the executing `Runnable`. Line 66 invokes `Future` method `get` to wait for the disconnect message to be delivered and the `Runnable` to terminate. Once the disconnect message has been delivered, line 67 invokes `PacketReceiver` method `stopListening` to stop receiving incoming chat messages. Line 68 closes the `Socket` connection to `DeitelMessengerServer`.

Figure 24.26. `MessageSender` for delivering outgoing messages to `DeitelMessengerServer`.

```

1 // Fig. 24.26: MessageSender.java
2 // Sends a message to the chat server in a separate runnable.
3 package com.deitel.messenger.sockets.client;
4
5 import java.io.IOException;
6 import java.util.Formatter;
7 import java.net.Socket;
8
9 import static com.deitel.messenger.sockets.SocketMessengerConstants.*;
10
11 public class MessageSender implements Runnable
12 {
13 private Socket clientSocket; // Socket over which to send message
14 private String messageToSend; // message to send
15
16 public MessageSender(Socket socket, String userName, String message)
17 {
18 clientSocket = socket; // store socket for client
19
20 // build message to be sent
21 messageToSend = userName + MESSAGE_SEPARATOR + message;
22 } // end MessageSender constructor
23
24 // send message and end
25 public void run()
26 {
27 try // send message and flush PrintWriter
28 {
29 Formatter output =
30 new Formatter(clientSocket.getOutputStream());
31 output.format("%s\n", messageToSend); // send message
32 output.flush(); // flush output
33 } // end try
34 catch (IOException ioException)
35 {
36 ioException.printStackTrace();
37 } // end catch
38 } // end method run
39 } // end class MessageSender

```

Method `sendMessage` (lines 8795) sends an outgoing message to the server. If `SocketMessageManager` is not connected, line 90 returns from method `sendMessage`. Lines 9394 create and start a new `MessageSender` ([Fig. 24.26](#)) to deliver the new message in a separate thread of execution.

Class `MessageSender` ([Fig. 24.26](#)), which implements `Runnable`, delivers outgoing messages to the server in a separate thread of execution. `MessageSender`'s constructor (lines 1622) takes as arguments the `Socket` over which to send the message, the `userName` from whom the message came and the message. Line 21 concatenates these arguments to build `messageToSend`. Constant `MESSAGE_SEPARATOR` enables the message recipient to parse the message into two parts: the sending user's name and the message body by using a `StringTokenizer`.

Method `run` (lines 2538) delivers the complete message to the server, using the `Socket` provided to the `MessageSender` constructor. Lines 2930 create a new `Formatter` for the `clientSocket`'s `OutputStream`. Line 31 invokes `Formatter` method `format` to send the message. Line 32 invokes method `flush` of class `Formatter` to

ensure that the message is sent immediately. Note that class `MessageSender` does not close the `clientSocket`. Class `SocketMessageManager` uses a new object of class `MessageSender` for each message the client sends, so the `clientSocket` must remain open until the user disconnects from `DeitelMessengerServer`.

---

[Page 1169]

Class `PacketReceiver` (Fig. 24.27) implements interface `Runnable` to enable `SocketMessageManager` to listen for incoming messages in a separate thread of execution. Line 18 declares the `MessageListener` to which `PacketReceiver` will deliver incoming messages. Line 19 declares a `MulticastSocket` for receiving multicast `DatagramPackets`. Line 20 declares an `InetAddress` reference for the multicast address to which `DeitelMessengerServer` posts new chat messages. The `MulticastSocket` connects to this `InetAddress` to listen for incoming chat messages.

Figure 24.27. `PacketReceiver` for listening for new multicast messages from `DeitelMessengerServer` in a separate thread.

(This item is displayed on pages 1169 - 1171 in the print version)

```
1 // Fig. 24.27: PacketReceiver.java

11 import java.util.StringTokenizer;
12
13 import com.deitel.messenger.MessageListener;
14 import static com.deitel.messenger.sockets.SocketMessengerConstants.*;
15
16 public class PacketReceiver implements Runnable
17 {
18 private MessageListener messageListener; // receives messages
19 private MulticastSocket multicastSocket; // receive broadcast messages
20 private InetAddress multicastGroup; // InetAddress of multicast group
21 private boolean keepListening = true; // terminates PacketReceiver
22
23 public PacketReceiver(MessageListener listener)
24 {
25 messageListener = listener; // set MessageListener
26
27 try // connect MulticastSocket to multicast address and port
28 {
29 // create new MulticastSocket
30 multicastSocket = new MulticastSocket(
31 MULTICAST_LISTENING_PORT);
32
33 // use InetAddress to get multicast group
34 multicastGroup = InetAddress.getByName(MULTICAST_ADDRESS);
35
36 // join multicast group to receive messages
37 multicastSocket.joinGroup(multicastGroup);
38
39 // set 5 second timeout when waiting for new packets
```

```
40 multicastSocket.setSoTimeout(5000);
41 } // end try
42 catch (IOException ioException)
43 {
44 ioException.printStackTrace();
45 } // end catch
46 } // end PacketReceiver constructor
47
48 // listen for messages from multicast group
49 public void run()
50 {
51 // listen for messages until stopped
52 while (keepListening)
53 {
54 // create buffer for incoming message
55 byte[] buffer = new byte[MESSAGE_SIZE];
56
57 // create DatagramPacket for incoming message
58 DatagramPacket packet = new DatagramPacket(buffer,
59 MESSAGE_SIZE);
60
61 try // receive new DatagramPacket (blocking call)
62 {
63 multicastSocket.receive(packet);
64 } // end try
65 catch (SocketTimeoutException socketTimeoutException)
66 {
67 continue; // continue to next iteration to keep listening
68 } // end catch
69 catch (IOException ioException)
70 {
71 ioException.printStackTrace();
72 break;
73 } // end catch
74
75 // put message data in a String
76 String message = new String(packet.getData());
77
78 message = message.trim(); // trim whitespace from message
79
80 // tokenize message to retrieve user name and message body
81 StringTokenizer tokenizer = new StringTokenizer(
82 message, MESSAGE_SEPARATOR);
83
84 // ignore messages that do not contain a user
85 // name and message body
86 if (tokenizer.countTokens() == 2)
87 {
88 // send message to MessageListener
89 messageListener.messageReceived(
90 tokenizer.nextToken(), // user name
91 tokenizer.nextToken()); // message body
92 } // end if
93 } // end while
94
95 try
96 {
97 multicastSocket.leaveGroup(multicastGroup); // leave group
98 multicastSocket.close(); // close MulticastSocket
99 } // end try
100 catch (IOException ioException)
```

```

101 {
102 IOException.printStackTrace();
103 } // end catch
104 } // end method run
105
106 // stop listening for new messages
107 public void stopListening()
108 {
109 keepListening = false;
110 } // end method stopListening
111 } // end class PacketReceiver

```

The `PacketReceiver` constructor (lines 2346) takes as an argument the `MessageListener` to which the `PacketReceiver` is to deliver incoming messages. Recall that interface `MessageListener` declares method `messageReceived`. When the `PacketReceiver` receives a new chat message over the `MulticastSocket`, `PacketReceiver` invokes `messageReceived` to deliver the new message to the `MessageListener`.

---

[Page 1171]

Lines 3031 create a new `MulticastSocket` and pass to the `MulticastSocket` constructor the constant `MULTICAST_LISTENING_PORT` from interface `SocketMessengerConstants`. This argument specifies the port on which the `MulticastSocket` will listen for incoming chat messages. Line 34 creates an `InetAddress` object for the `MULTICAST_ADDRESS`, to which `DeitelMessengerServer` multicasts new chat messages. Line 37 invokes `MulticastSocket` method `joinGroup` to register the `MulticastSocket` to receive messages sent to `MULTICAST_ADDRESS`. Line 40 invokes `MulticastSocket` method `setSoTimeout` to specify that if no data is received in 5000 milliseconds, the `MulticastSocket` should issue an `InterruptedException`, which the current thread can catch, then continue executing. This approach prevents `PacketReceiver` from blocking indefinitely when waiting for incoming data. Also, if the `MulticastSocket` never timed out, the `while` loop would not be able to check the `keepListening` variable and would therefore prevent `PacketReceiver` from stopping if `keepListening` were set to `false`.

Method `run` (lines 49104) listens for incoming multicast messages. Lines 5859 create a `DatagramPacket` to store the incoming message. Line 63 invokes `MulticastSocket` method `receive` to read an incoming packet from the multicast address. If 5000 milliseconds pass without receipt of a packet, method `receive` throws an `InterruptedException`, because we previously set a 5000-millisecond time-out (line 40). Line 67 uses `continue` to proceed to the next loop iteration to listen for incoming messages. For other `IOExceptions`, line 72 breaks the `while` loop to terminate the `PacketReceiver`.

---

[Page 1172]

Line 76 invokes `DatagramPacket` method `getData` to retrieve the message data. Line 78 invokes method `trim` of class `String` to remove extra white space from the end of the message. Recall that `DatagramPackets` are of a fixed size 512 bytes in this example so, if the message is shorter than 512 bytes, there will be extra white space after it. Lines 8182 create a `StringTokenizer` to separate the message body from the name of the user who sent the message. Line 86 checks for the correct number of tokens. Lines 8991 invoke method `messageReceived` of interface `MessageListener` to deliver the incoming message to the `PacketReceiver`'s `MessageListener`.

If the program invokes method `stopListening` (lines 107110), the `while` loop in method `run` (lines 49104) terminates. Line 97 invokes `MulticastSocket` method `leaveGroup` to stop receiving messages from the multicast address. Line 98 invokes `MulticastSocket` method `close` to close the `MulticastSocket`. When method `run` completes execution, the `PacketReceiver` terminates.

Class `ClientGUI` (Fig. 24.28) extends class `JFrame` to create a GUI for a user to send and receive chat messages. The GUI consists of a `JTextArea` for displaying incoming messages (line 31), a `JTextArea` for entering new messages (line 32), `JButtons` and `JMenuItems` for connecting to and disconnecting from the server (lines 3336) and a `JButton` for sending messages (line 37). The GUI also contains a `JLabel` that

displays whether the client is connected or disconnected (line 38).

221 private class MessageDisplay implements Runnable
222 {
223 private String fromUser; // user from which message came
224 private String messageBody; // body of message
225
226 // MessageDisplay constructor
227 public MessageDisplay(String from, String body)
228 {
229 fromUser = from; // store originating user
230 messageBody = body; // store message body
231 } // end MessageDisplay constructor
232

```

```

233 // display new message in messageArea
234 public void run()
235 {
236 // append new message
237 messageArea.append("\n" + fromUser + "> " + messageBody);
238 } // end method run
239 } // end MessageDisplayer inner class
240 } // end class ClientGUI

```

`ClientGUI` uses a `MessageManager` (line 40) to handle all communication with the chat server. Recall that `MessageManager` is an interface that enables `ClientGUI` to use any `MessageManager` implementation. Class `ClientGUI` also uses a `MessageListener` (line 41) to receive incoming messages from the `MessageManager`.

The `ClientGUI` constructor (lines 44-60) takes as an argument the `MessageManager` for communicating with `DeitelMessengerServer`. Line 48 sets the `ClientGUI`'s `MessageManager`. Line 51 creates an instance of `MyMessageListener`, which implements interface `MessageListener`. Lines 53-57 create a **Server** menu that contains `JMenuItems` for connecting to and disconnecting from the chat server. Lines 60-61 create an `ImageIcon` for `connectButton` and `connectMenuItem`.

Lines 64-65 create `connectButton` and `connectMenuItem`, each with the label "Connect" and the `Icon` `connectIcon`. Line 66 invokes method `setMnemonic` to set the mnemonic character for keyboard access to `connectMenuItem`. Line 69 creates an instance of inner class `ConnectListener` (declared at lines 163-185), which implements interface `ActionListener` to handle `ActionEvents` from `connectButton` and `connectMenuItem`. Lines 70-71 add `connectListener` as an `ActionListener` for `connectButton` and `connectMenuItem`.

Lines 74-75 create an `ImageIcon` for the `disconnectButton` and `disconnectMenuItem` components. Lines 78-79 create `disconnectButton` and `disconnectMenuItem`, each with the label "Disconnect" and the `Icon` `disconnectIcon`. Line 80 invokes method `setMnemonic` to enable keyboard access to `disconnectMenuItem`. Lines 83-84 invoke method `setEnabled` with a `false` argument on `disconnectButton` and `disconnectMenuItem` to disable these components. This prevents the user from attempting to disconnect from the server because the client is not yet connected. Line 87 creates an instance of inner class `DisconnectListener` (declared at lines 189-204), which implements interface `ActionListener` to handle `ActionEvents` from `disconnectButton` and `disconnectMenuItem`. Lines 88-89 add `disconnectListener` as an `ActionListener` for `disconnectButton` and `disconnectMenuItem`.

Lines 92-93 add `connectMenuItem` and `disconnectMenuItem` to menu **Server**. Lines 96-98 create a `JPanel` and add `connectButton` and `disconnectButton` to it. Line 100 creates the text area `messageArea`, in which the client displays incoming messages. Line 101 invokes method `setEditable` with a `false` argument, to disable editing. Lines 102-103 invoke `JTextArea` methods `setWrapStyleWord` and `setLineWrap` to enable word wrapping in `messageArea`. If a message is longer than `messageArea`'s width, the `messageArea` will wrap the text after the last word that fits on each line, making longer messages easier to read. Lines 106-109 create a `JPanel` for the `messageArea` and add the `messageArea` to the `JPanel` in a `JScrollPane`.

---

[Page 1178]

Line 111 creates the `inputArea` `JTextArea` for entering new messages. Lines 112-113 enable word and line wrapping, and line 114 disables editing the `inputArea`. When the client connects to the chat server, `ConnectListener` enables the `inputArea` to allow the user to type new messages.

Lines 117-118 create an `ImageIcon` for `sendButton`. Line 120 creates `sendButton`, which the user can click to send a message. Line 121 disables `sendButton` the `ConnectListener` enables the `sendButton` when the client connects to the chat server. Lines 122-133 add an `ActionListener` to `sendButton`. Lines 128-129 invoke method `sendMessage` of interface `MessageManager` with the `userName` and `inputArea` text as arguments. This statement sends the user's name and message as a new chat message to `DeitelMessengerServer`. Line 130 clears the `inputArea` for the next message.

Lines 135-138 use a horizontal `Box` container to arrange components `inputArea` and `sendButton`. Line 136

places `inputArea` in a `JScrollPane` to enable scrolling of long messages. Line 138 adds the `Box` containing `inputArea` and `sendButton` to the `SOUTH` region of `messagePanel`. Line 141 creates the `statusBar JLabel`. This label displays whether the client is connected to or disconnected from the chat server. Line 142 invokes method `setBorder` of class `JLabel` and creates a new `BevelBorder` of type `BevelBorder.LOWERED`. This `border` makes the label appear recessed, as is common with status bars in many applications. Lines 144-146 add `buttonPanel`, `messagePanel` and `statusBar` to the `ClientGUI`.

Lines 149-159 add a `WindowListener` to the `ClientGUI`. Line 155 invokes method `disconnect` of interface `MessageManager` to disconnect from the chat server in case the user quits while still connected. Then line 156 terminates the application.

Inner class `ConnectListener` (lines 163-185) handles events from `connectButton` and `connectMenuItem`. Line 169 invokes `MessageManager` method `connect` to connect to the chat server. Line 169 passes as an argument to method `connect` the `MessageListener` to which new messages should be delivered. Lines 172-173 prompt the user for a user name, and line 175 clears the `messageArea`. Lines 176-181 enable the components for disconnecting from the server and for sending messages and disable the components for connecting to the server. Line 182 invokes `inputArea`'s `requestFocus` method (inherited from class `Component`) to place the text-input cursor in the `inputArea` so that the user can immediately begin typing a message.

Inner class `DisconnectListener` (lines 189-204) handles events from `disconnectButton` and `disconnectMenuItem`. Line 195 invokes `MessageManager` method `disconnect` to disconnect from the chat server. Lines 196-201 disable the components for sending messages and the components for disconnecting, then enable the components for connecting to the chat server.

Inner class `MyMessageListener` (lines 208-217) implements interface `MessageListener` to receive incoming messages from the `MessageManager`. When a new message is received, the `MessageManager` invokes method `messageReceived` (lines 211-216) with the user name of the sender and the message body. Lines 214-215 invoke `SwingUtilities` method `invokeLater` with a `MessageDisplayer` object that appends the new message to `messageArea`. Recall, from [Chapter 23](#), that Swing components should be accessed only from the event-dispatch thread. Method `messageReceived` is invoked by the `PacketReceiver` in class `SocketMessageManager` and therefore cannot append the message text to `messageArea` directly, as this would occur in `PacketReceiver`, not the event-dispatch thread.

---

[Page 1179]

Inner class `MessageDisplayer` (lines 221-239) implements interface `Runnable` to provide a thread-safe way to append text to the `messageArea`. The `MessageDisplayer` constructor (lines 227-231) takes as arguments the user name and the message to send. Method `run` (lines 234-238) appends the user name, "> " and `messageBody` to `messageArea`.

Class `DeitelMessenger` ([Fig. 24.29](#)) launches the client for the `DeitelMessengerServer`. Lines 1520 create a new `SocketMessageManager` to connect to the `DeitelMessengerServer` with the IP address specified as a command-line argument to the application (or `localhost`, if no address is provided). Lines 2326 create a `ClientGUI` for the `MessageManager`, set the `ClientGUI` size and make the `ClientGUI` visible.

**Figure 24.29. `DeitelMessenger` application for participating in a `DeitelMessengerServer` chat session.**

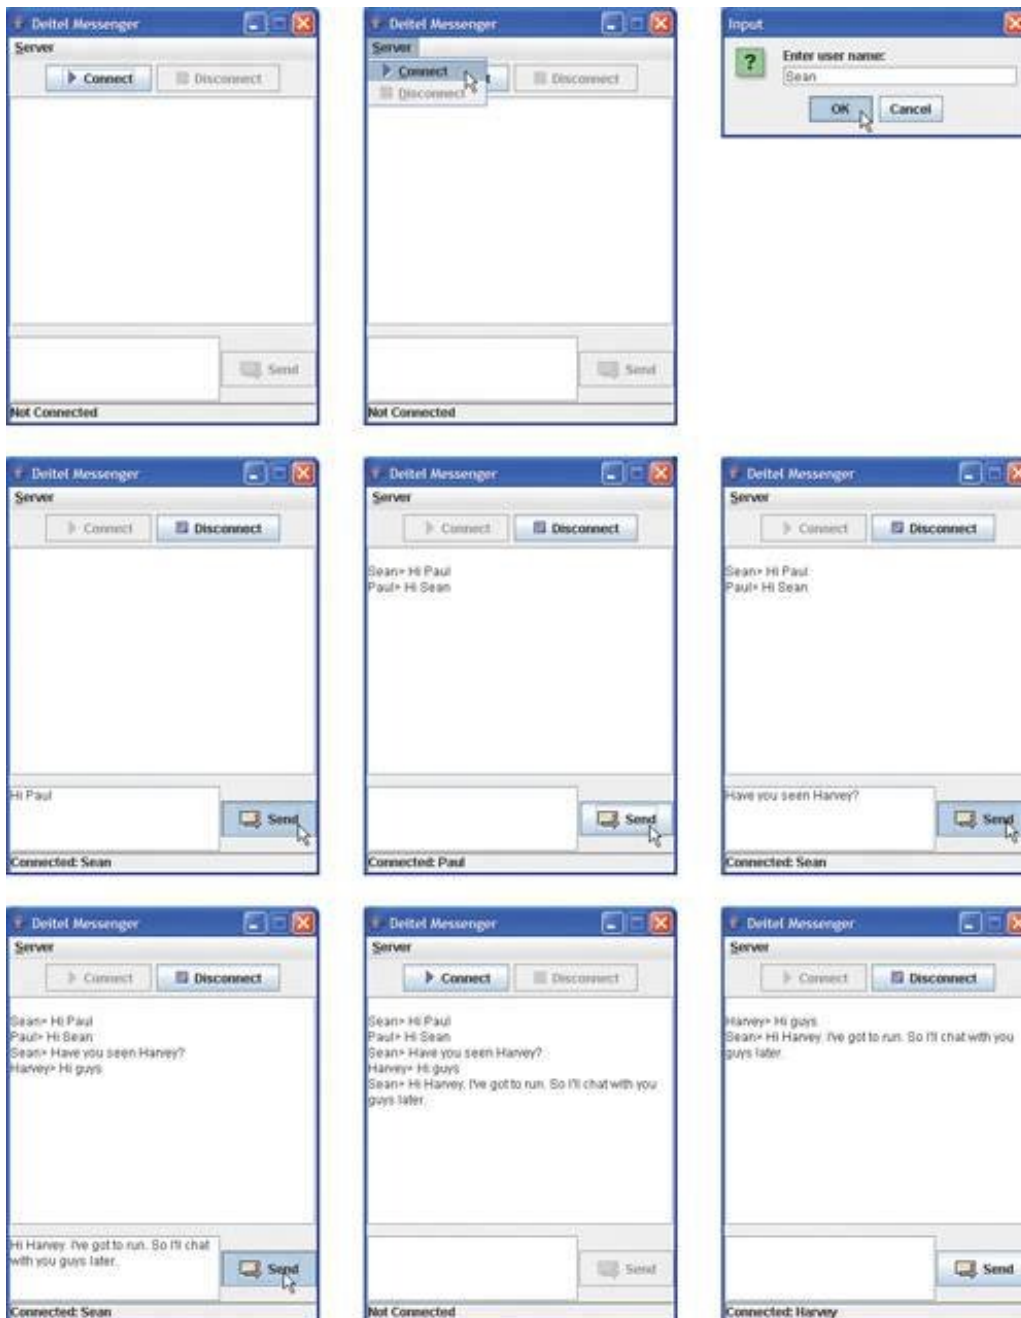

(This item is displayed on pages 1179 - 1180 in the print version)

```
1 // Fig. 24.29: DeitelMessenger.java
2 // DeitelMessenger is a chat application that uses a ClientGUI
3 // and SocketMessageManager to communicate with DeitelMessengerServer.
4 package com.deitel.messenger.sockets.client;
5
6 import com.deitel.messenger.MessageManager;
7 import com.deitel.messenger.ClientGUI;
8
```

```
9 public class DeitelMessenger
10 {
11 public static void main(String args[])
12 {
13 MessageManager messageManager; // declare MessageManager
14
15 if (args.length == 0)
16 // connect to localhost
17 messageManager = new SocketMessageManager("localhost");
18 else
19 // connect using command-line arg
20 messageManager = new SocketMessageManager(args[0]);
21
22 // create GUI for SocketMessageManager
23 ClientGUI clientGUI = new ClientGUI(messageManager);
24 clientGUI.setSize(300, 400); // set window size
25 clientGUI.setResizable(false); // disable resizing
26 clientGUI.setVisible(true); // show window
27 } // end main
28 } // end class DeitelMessenger
```

[\[View full size image\]](#)

[Page 1180]

## Executing the DeitelMessenger Client Application

To execute the `DeitelMessenger` client, open a command window and change directories to the location in which package `com.deitel.messenger.sockets.client` resides (i.e., the directory in which `com` is located). Then type

[Page 1181]

```
java com.deitel.messenger.sockets.client.DeitelMessenger
```

to execute the client and connect to the `DeitelMessengerServer` running on your local computer. If the server resides on another computer, follow the preceding command with the hostname or IP address of that

computer. The preceding command is equivalent to

```
java com.deitel.messenger.sockets.client.DeitelMessenger localhost
```

or

```
java com.deitel.messenger.sockets.client.DeitelMessenger 127.0.0.1
```

## Deitel Messenger Case Study Summary

The Deitel messenger case study is a significant application that uses many intermediate Java features, such as networking with `SocketS`, `DatagramPackets` and `MulticastSockets`, multithreading and Swing GUI. The case study also demonstrates good software engineering practices by separating interface from implementation, enabling developers to build `MessageManagers` for different network protocols and `MessageListeners` that provide different user interfaces. You should now be able to apply these techniques to your own, more complex, Java projects.

## 24.11. Wrap-Up

In this chapter, you have learned the basics of network programming in Java. You learned two different methods of sending data over a network: streams-based networking using TCP/IP and datagrams-based networking using UDP. You also learned about multicasting, which allows you to send data to multiple clients with a single command. In the next chapter, you will learn basic database concepts, how to interact with data in a database using SQL and how to use JDBC to allow Java applications to manipulate database data.

## Summary

- Java provides stream sockets and datagram sockets. With stream sockets, a process establishes a connection to another process. While the connection is in place, data flows between the processes in streams. Stream sockets are said to provide a connection-oriented service. The protocol used for transmission is the popular TCP (Transmission Control Protocol).
- With datagram sockets, individual packets of information are transmitted. UDP (User Datagram Protocol) is a connectionless service that does not guarantee that packets will not be lost, duplicated or arrive out of sequence. Extra programming is required on the programmer's part to deal with these problems.
- The HTTP protocol (Hypertext Transfer Protocol) that forms the basis of the Web uses URIs (Uniform Resource Identifiers) to locate data on the Internet. Common URIs represent files or directories and can represent complex tasks such as database lookups and Internet searches. A URI that represents a document is called a URL (Uniform Resource Locator).
- Web browsers often restrict an applet so that it can communicate only with the machine from which it was originally downloaded.
- `Applet` method `getAppletContext` returns a reference to an `AppletContext` object that represents the applet's environment (i.e., the browser in which the applet is executing). `AppletContext` method `showDocument` receives a `URL` as an argument and passes it to the `AppletContext` (i.e., the browser), which displays the Web resource associated with that `URL`. A second version of `showDocument` enables an applet to specify the target frame in which to display a Web resource. Special target frames include `_blank` (display in a new Web browser window), `_self` (display in the same frame as the applet) and `_top` (remove the current frames, then display in the current window).

- `JEditorPane` method `setPage` downloads the document specified by its argument and displays it in the `JEditorPane`.
- Typically, an HTML document contains hyperlink text, images or GUI components that, when clicked, link to another document on the Web. If an HTML document is displayed in a `JEditorPane` and the user clicks a hyperlink, the `JEditorPane` generates a `HyperlinkEvent` and notifies all registered `HyperlinkListeners` of the event.
- `HyperlinkEvent` method `getEventType` determines the event type. `HyperlinkEvent` contains nested class `EventType`, which declares three hyperlink event types: `ACTIVATED` (hyperlink clicked), `ENTERED` (mouse over a hyperlink) and `EXITED` (mouse moved away from a hyperlink). `HyperlinkEvent` method `getURL` obtains the `URL` represented by the hyperlink.
- Stream-based connections are managed with `Socket` objects.
- A `ServerSocket` object establishes the port where a server waits for connections from clients. The second argument to the `ServerSocket` constructor is the number of connections that can wait in a queue to connect to the server. If the queue of clients is full, client connections are refused. The `ServerSocket` method `accept` waits indefinitely (i.e., blocks) for a connection from a client and returns a `Socket` object when a connection is established.
- `Socket` methods `getOutputStream` and `getInputStream` get references to a `Socket`'s `OutputStream` and `InputStream`, respectively. `Socket` method `close` terminates a connection.
- A server name and port number are specified when creating a `Socket` object to enable it to connect a

client to the server. A failed connection attempt throws an `IOException`.

- `InetAddress` method `getByName` returns an `InetAddress` object containing the host name of the computer for which the host name or IP address is specified as an argument. `InetAddress` method `getLocalHost` returns an `InetAddress` object containing the host name of the local computer executing the program.
  - Connection-oriented transmission is like the telephone system you dial and are given a connection to the telephone of the person with whom you wish to communicate. The connection is maintained for the duration of your phone call, even when you are not talking.
  - Connectionless transmission with datagrams is similar to mail carried via the postal service. A large message that will not fit in one envelope can be broken into separate message pieces that are placed in separate, sequentially numbered envelopes. All the letters are then mailed at once. They could arrive in order, out of order or not at all.
  - `DatagramPacket` objects store packets of data that are to be sent or that are received by an application. `DatagramSockets` send and receive `DatagramPackets`.
  - The `DatagramSocket` constructor that takes no arguments binds the application to a port chosen by the computer on which the program executes. The `DatagramSocket` constructor that takes an integer port number argument binds the application to the specified port. If a `DatagramSocket` constructor fails to bind the application to a port, a `SocketException` occurs. `DatagramSocket` method `receive` blocks (waits) until a packet arrives, then stores the packet in its argument.
  - `DatagramPacket` method `getAddress` returns an `InetAddress` object containing information about the host computer from which the packet was sent. Method `getPort` returns an integer specifying the port number through which the host computer sent the `DatagramPacket`. Method `getLength` returns an integer representing the number of bytes of data in a `DatagramPacket`. Method `getData` returns a byte array containing the data in a `DatagramPacket`.
- 

[Page 1183]

- The `DatagramPacket` constructor for a packet to be sent takes four arguments: the byte array to be sent, the number of bytes to be sent, the client address to which the packet will be sent and the port number where the client is waiting to receive packets.
- `DatagramSocket` method `send` sends a `DatagramPacket` out over the network.
- If an error occurs when receiving or sending a `DatagramPacket`, an `IOException` occurs.
- Reading data from a `Socket` is a blocking call: the current thread is put in the blocked state while it waits for the read operation to complete. Method `setSoTimeout` specifies that if no data is received in the given number of milliseconds, the `Socket` is to issue an `InterruptedIOException`, which the current thread can catch, then continue executing. This prevents the current thread from blocking indefinitely if no more data is available from the `Socket`.
- Multicast is an efficient way to send data to many clients without the overhead of broadcasting it to every host on the Internet. Using multicast, an application can "publish" `DatagramPackets` to be delivered to subscriber applications. An application multicasts `DatagramPackets` by sending them to a multicast address: an IP address in the range from 224.0.0.0 to 239.255.255.255, reserved for multicast.
- Clients that wish to receive `DatagramPackets` can join the multicast group that will receive the `DatagramPackets` published to the multicast address.
- Multicast `DatagramPackets` are not reliable: packets are not guaranteed to reach any destination or to arrive in any particular order.
- The `MulticastSocket` constructor takes as an argument the port to which the `MulticastSocket` connects to receive incoming `DatagramPackets`.

- Method `joinGroup` of class `MulticastSocket` takes as an argument the `InetAddress` of the multicast group to join. Method `receive` of class `MulticastSocket` reads an incoming `DatagramPacket` from a multicast address.

## Self-Review Exercises

24.1 Fill in the blanks in each of the following statements:

- a. Exception \_\_\_\_\_ occurs when an input/output error occurs when closing a socket.
- b. Exception \_\_\_\_\_ occurs when a host name indicated by a client cannot be resolved to an address.
- c. If a `DatagramSocket` constructor fails to set up a `DatagramSocket` properly, an exception of type \_\_\_\_\_ occurs.
- d. Many of Java's networking classes are contained in package \_\_\_\_\_.
- e. Class \_\_\_\_\_ binds the application to a port for datagram transmission.
- f. An object of class \_\_\_\_\_ contains an IP address.
- g. The two types of sockets we discussed in this chapter are \_\_\_\_\_ and \_\_\_\_\_.
- h. The acronym URL stands for \_\_\_\_\_.
- i. The acronym URI stands for \_\_\_\_\_.
- j. The key protocol that forms the basis of the World Wide Web is \_\_\_\_\_.
- k. `AppletContext` method \_\_\_\_\_ receives a `URL` object as an argument and displays in a browser the World Wide Web resource associated with that `URL`.

---

[Page 1185]

- l. Method `getLocalHost` returns a(n) \_\_\_\_\_ object containing the local host name of the computer on which the program is executing.
- m. `MulticastSocket` method \_\_\_\_\_ subscribes a `MulticastSocket` to a multicast group.
- n. The `URL` constructor determines whether its string argument is a valid URL. If so, the `URL` object is initialized with that location. If not, a(n) \_\_\_\_\_ exception occurs.

24.2 State whether each of the following is *true or false*. If *false*, explain why.

- a. Multicast broadcasts `DatagramPacket`s to every host on the Internet.
- b. UDP is a connection-oriented protocol.
- c. With stream sockets a process establishes a connection to another process.
- d. A server waits at a port for connections from a client.
- e. Datagram packet transmission over a network is reliable; packets are guaranteed to arrive in sequence.

- f. For security reasons, many Web browsers, such as Mozilla, allow Java applets to do file processing only on the machines on which they execute.
- g. Web browsers often restrict an applet so that it can only communicate with the machine from which it was originally downloaded.
- h. IP addresses from `224.0.0.0` to `239.255.255.255` are reserved for multicast.

## Answers to Self-Review Exercises

24.1 a) `IOException`. b) `UnknownHostException`. c) `SocketException`. d) `java.net`. e) `DatagramSocket`. f) `InetAddress`. g) stream sockets, datagram sockets. h) Uniform Resource Locator. i) Uniform Resource Identifier. j) HTTP. k) `showDocument`. l) `InetAddress`. m) `joinGroup`. n) `MalformedURLException`.

24.2 a) False; multicast sends `DatagramPackets` only to hosts that have joined the multicast group. b) False; UDP is a connectionless protocol and TCP is a connection-oriented protocol. c) True. d) True. e) False; packets can be lost, arrive out of order or be duplicated. f) False; most browsers prevent applets from doing file processing on the client machine. g) True. h) True.

## Exercises

- 24.3 Distinguish between connection-oriented and connectionless network services.
- 24.4 How does a client determine the host name of the client computer?
- 24.5 Under what circumstances would a `SocketException` be thrown?
- 24.6 How can a client get a line of text from a server?
- 24.7 Describe how a client connects to a server.
- 24.8 Describe how a server sends data to a client.
- 24.9 Describe how to prepare a server to receive a stream-based connection request from a single client.
- 24.10 How does a server listen for streams-based socket connections at a port?
- 24.11 What determines how many connect requests from clients can wait in a queue to connect to a server?
- 24.12 As described in the text, what reasons might cause a server to refuse a connection request from a client?
- 24.13 Use a socket connection to allow a client to specify a file name and have the server send the contents of the file or indicate that the file does not exist.

---

[Page 1186]

- 24.14 Modify [Exercise 24.13](#) to allow the client to modify the contents of the file and send the file back to the server for storage. The user can edit the file in a `JTextArea`, then click a *save changes* button to send the file back to the server.
- 24.15 Modify the program in [Fig. 24.2](#) to allow users to add their own sites to the list and remove sites from the list.
- 24.16 Multithreaded servers are quite popular today, especially because of the increasing use of multiprocessing servers. Modify the simple server application presented in [Section 24.6](#) to be a multithreaded server. Then use several client applications and have each of them connect to the server simultaneously. Use an `ArrayList` to store the client threads. `ArrayList` provides several methods of use in this exercise. Method `size` determines the number of elements in an `ArrayList`. Method `get` returns the element in the location specified by its argument. Method `add` places its argument at the end of the `ArrayList`. Method `remove` deletes its argument from the `ArrayList`.
- 24.17 (*Checkers Game*) In the text, we presented a Tic-Tac-Toe program controlled by a multithreaded server. Develop a checkers program modeled after the Tic-Tac-Toe program. The two users should alternate making moves. Your program should mediate the players' moves, determining whose turn it is and allowing only valid moves. The players themselves will determine when the game is over.

- 24.18 (*Chess Game*) Develop a chess-playing program modeled after the checkers program in the [Exercise 24.17](#).
- 24.19 (*Blackjack Game*) Develop a blackjack card game program in which the server application deals cards to each of the client applets. The server should deal additional cards (as per the rules of the game) to each player as requested.
- 24.20 (*Poker Game*) Develop a poker card game in which the server application deals cards to each of the client applets. The server should deal additional cards (as per the rules of the game) to each player as requested.
- 24.21 (*Modifications to the Multithreaded Tic-Tac-Toe Program*) The programs in [Fig. 24.13](#) and [Fig. 24.15](#) implemented a multithreaded, client/server version of the game of Tic-Tac-Toe. Our goal in developing this game was to demonstrate a multithreaded server that could process multiple connections from clients at the same time. The server in the example is really a mediator between the two client applets; it makes sure that each move is valid and that each client moves in the proper order. The server does not determine who won or lost or whether there was a draw. Also, there is no capability to allow a new game to be played or to terminate an existing game.

The following is a list of suggested modifications to [Fig. 24.13](#) and [Fig. 24.15](#):

- a. Modify the `TicTacToeServer` class to test for a win, loss or draw on each move in the game. Send a message to each client applet that indicates the result of the game when the game is over.
- b. Modify the `TicTacToeClient` class to display a button that when clicked allows the client to play another game. The button should be enabled only when a game completes. Note that both class `TicTacToeClient` and class `TicTacToeServer` must be modified to reset the board and all state information. Also, the other `TicTacToeClient` should be notified that a new game is about to begin so that its board and state can be reset.
- c. Modify the `TicTacToeClient` class to provide a button that allows a client to terminate the program at any time. When the user clicks the button, the server and the other client should be notified. The server should then wait for a connection from another client so that a new game can begin.
- d. Modify the `TicTacToeClient` class and the `TicTacToeServer` class so that the winner of a game can choose game piece X or O for the next game. Remember: X always goes first.

---

[Page 1187]

- e. If you would like to be ambitious, allow a client to play against the server while the server waits for a connection from another client.
- 24.22 (*3-D Multithreaded Tic-Tac-Toe*) Modify the multithreaded, client/server Tic-Tac-Toe program to implement a three-dimensional 4-by-4-by-4 version of the game. Implement the server application to mediate between the two clients. Display the three-dimensional board as four boards containing four rows and four columns each. If you would like to be ambitious, try the following modifications:
- a. Draw the board in a three-dimensional manner.
  - b. Allow the server to test for a win, loss or draw. Beware! There are many possible ways to win on a 4-by-4-by-4 board!
- 24.23 (*Networked Morse Code*) Perhaps the most famous of all coding schemes is the Morse code,

developed by Samuel Morse in 1832 for use with the telegraph system. The Morse code assigns a series of dots and dashes to each letter of the alphabet, each digit, and a few special characters (e.g., period, comma, colon and semicolon). In sound-oriented systems, the dot represents a short sound and the dash represents a long sound. Other representations of dots and dashes are used with light-oriented systems and signal-flag systems. Separation between words is indicated by a space or, simply, the absence of a dot or dash. In a sound-oriented system, a space is indicated by a short time during which no sound is transmitted. The international version of the Morse code appears in [Fig. 24.30](#).

Figure 24.30. The letters of the alphabet as expressed in international Morse code.

| Character | Code  | Character     | Code   |
|-----------|-------|---------------|--------|
| A         | .-    | T             | -      |
| B         | -...  | U             | ..-    |
| C         | -.-.  | V             | ...-   |
| D         | -..   | W             | .-.-   |
| E         | .     | X             | -..-   |
| F         | ..-.  | Y             | -.-.-  |
| G         | --.   | Z             | --..   |
| H         | ....  |               |        |
| I         | ..    | <i>Digits</i> |        |
| J         | .---- | 1             | .----- |
| K         | -.-   | 2             | ..---- |
| L         | .-... | 3             | ...--  |
| M         | --    | 4             | ....-  |
| N         | -.    | 5             | .....  |
| O         | ---   | 6             | -..... |
| P         | .-.-. | 7             | --.... |
| Q         | --.-  | 8             | ----.. |
| R         | .-.   | 9             | -----. |
| S         | ...   | 0             | -----  |

Write a client/server application in which two clients can send Morse code messages to each other through a multithreaded server application. The client application should allow the user to type English-language phrases in a `JTextArea`. When the user sends the message, the client application encodes the text into Morse code and sends the coded message through the server to the other client. Use one blank between each Morse-coded letter and three blanks between each Morse-coded word. When messages are received, they should be decoded and displayed

as normal characters and as Morse code. The client should have one `TextField` for typing and one `TextArea` for displaying the other client's messages.

# Chapter 25. Accessing Databases with JDBC

*It is a capital mistake to theorize before one has data.*

Arthur Conan Doyle

*Now go, write it before them in a table, and note it in a book, that it may be for the time to come for ever and ever.*

The Holy Bible, Isaiah 30:8

*Get your facts first, and then you can distort them as much as you please.*

Mark Twain

*I like two kinds of men: domestic and foreign.*

Mae West

## OBJECTIVES

In this chapter you will learn:

- Relational database concepts.
- To use Structured Query Language (SQL) to retrieve data from and manipulate data in a database.
- To use the JDBC™ API of package `java.sql` to access databases.

## Outline

### [25.1](#) Introduction

### [25.2](#) Relational Databases

### [25.3](#) Relational Database Overview: The `books` Database

### [25.4](#) SQL

#### [25.4.1](#) Basic `SELECT` Query

#### [25.4.2](#) `WHERE` Clause

#### [25.4.3](#) `ORDER BY` Clause

#### [25.4.4](#) Merging Data from Multiple Tables: `INNER JOIN`

#### [25.4.5](#) `INSERT` Statement

#### [25.4.6](#) `UPDATE` Statement

#### [25.4.7](#) `DELETE` Statement

## 25.1. Introduction

A [database](#) is an organized collection of data. There are many different strategies for organizing data to facilitate easy access and manipulation. A [database management system \(DBMS\)](#) provides mechanisms for storing, organizing, retrieving and modifying data for many users. Database management systems allow for the access and storage of data without concern for the internal representation of data.

Today's most popular database systems are [relational databases](#). A language called [SQL](#) pronounced "sequel," or as its individual letters is the international standard language used almost universally with relational databases to perform [queries](#) (i.e., to request information that satisfies given criteria) and to manipulate data. [*Note:* As you learn about SQL, you will see some authors writing "a SQL statement" (which assumes the pronunciation "sequel") and others writing "an SQL statement" (which assumes that the individual letters are pronounced). In this book we pronounce SQL as "sequel." Thus the article preceding SQL is "a," as in "a SQL statement."]

Some popular [relational database management systems \(RDBMSs\)](#) are Microsoft SQL Server, Oracle, Sybase, IBM DB2, Informix, PostgreSQL and MySQL. In this chapter, we present examples using MySQL, which is located on the CD that accompanies this book and can also be downloaded from [dev.mysql.com/downloads/mysql/4.0.html](http://dev.mysql.com/downloads/mysql/4.0.html). MySQL is open source and is available for both Windows and Linux. [*Note:* We discuss basic MySQL features required to execute the examples in this chapter. Please refer to the detailed MySQL documentation for complete information on using MySQL.]

Java programs communicate with databases and manipulate their data using the [JDBC™ API](#). A [JDBC driver](#) enables Java applications to connect to a database in a particular DBMS and allows programmers to manipulate that database using the JDBC API. JDBC is almost always used with a relational database. However, it can be used with any table-based data source.

### Software Engineering Observation 25.1

*The separation of the JDBC API from particular database drivers enables developers to change the underlying database without modifying the Java code that accesses the database.*

Most popular database management systems now provide JDBC drivers. There are also many third-party JDBC drivers available. In this chapter, we introduce JDBC and use it to manipulate a MySQL database. The techniques demonstrated here can also be used to manipulate other databases that have JDBC drivers. Check your system's documentation to determine whether your DBMS comes with a JDBC driver. If not, many third-party vendors provide JDBC drivers for a wide variety of databases.

For more information on JDBC, visit

[java.sun.com/products/jdbc](http://java.sun.com/products/jdbc)

This site contains information concerning JDBC, including the JDBC specification, JDBC FAQs, a learning resource center and software downloads. For a list of available JDBC drivers, visit

This site provides a search engine to help you locate drivers appropriate to your DBMS.

## 25.2. Relational Databases

A [relational database](#) is a logical representation of data that allows the data to be accessed without consideration of its physical structure. A relational database stores data in [tables](#). [Figure 25.1](#) illustrates a sample table that might be used in a personnel system. The table name is `Employee`, and its primary purpose is to store the attributes of an employee. Tables are composed of [rows](#), and rows are composed of [columns](#) in which values are stored. This table consists of six rows. The `Number` column of each row in this table is the table's [primary key](#) a column (or group of columns) in a table with a unique value that cannot be duplicated in other rows. This guarantees that each row can be identified by its primary key. Good examples of primary key columns are a Social Security number, an employee ID number and a part number in an inventory system, as values in each of these columns are guaranteed to be unique. The rows in [Fig. 25.1](#) are displayed in order by primary key. In this case, the rows are listed in increasing order, but we could also use decreasing order. Rows in tables are not guaranteed to be stored in any particular order. As we will demonstrate in an upcoming example, programs can specify ordering criteria when requesting data from a database.

Figure 25.1. `Employee` table sample data.

(This item is displayed on page 1192 in the print version)

[\[View full size image\]](#)

|       | Number      | Name     | Department | Salary | Location    |
|-------|-------------|----------|------------|--------|-------------|
|       | 23603       | Jones    | 413        | 1100   | New Jersey  |
|       | 24568       | Kerwin   | 413        | 2000   | New Jersey  |
| Row { | 34589       | Larson   | 642        | 1800   | Los Angeles |
|       | 35761       | Myers    | 611        | 1400   | Orlando     |
|       | 47132       | Neumann  | 413        | 9000   | New Jersey  |
|       | 78321       | Stephens | 611        | 8500   | Orlando     |
|       | Primary key |          | Column     |        |             |

[Page 1192]

Each column represents a different data attribute. Rows are normally unique (by primary key) within a table, but particular column values may be duplicated between rows. For example, three different rows in the `Employee` table's `Department` column contain number 413.

Different users of a database are often interested in different data and different relationships among the data. Most users require only subsets of the rows and columns. To obtain these subsets, we use queries to specify which data to select from a table. Programmers use SQL to define complex queries that select data from a table. For example, we might select data from the `Employee` table to create a result that shows where each department is located. This result is shown in [Fig. 25.2](#). SQL queries are discussed in [Section 25.4](#).

Figure 25.2. Result of selecting distinct `Department`

and **Location** data  
from table  
**Employee**.

| Department | Location   |
|------------|------------|
| 413        | New Jersey |
| 611        | Orlando    |

## 25.3. Relational Database Overview: The **books** Database

This section overviews relational databases in the context of a sample **books** database we created for this chapter. Before we discuss SQL, we overview the tables of the **books** database. We use this database to introduce various database concepts, including how to use SQL to obtain information from the database and to manipulate the data. We provide a script to create the database. You can find the script in the examples directory for this chapter on the CD that accompanies this book. [Section 25.5](#) explains how to use this script.

The database consists of four tables: **authors**, **publishers**, **authorISBN** and **titles**. The **authors** table (described in [Fig. 25.3](#)) consists of three columns that maintain each author's unique ID number, first name and last name. [Figure 25.4](#) contains sample data from the **authors** table of the **books** database.

Figure 25.3. **authors** table from **books**.

| Column           | Description                                                                                                                                                                                                                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>authorID</b>  | Author's ID number in the database. In the <b>books</b> database, this integer column is defined as <b>autoincremented</b> . For each row inserted in this table, the <b>authorID</b> value is increased by 1 automatically to ensure that each row has a unique <b>authorID</b> . This column represents the table's primary key. |
| <b>firstName</b> | Author's first name (a string).                                                                                                                                                                                                                                                                                                    |
| <b>lastName</b>  | Author's last name (a string).                                                                                                                                                                                                                                                                                                     |

Figure 25.4. Sample data from the **authors** table.

| <b>authorID</b> | <b>firstName</b> | <b>lastName</b> |
|-----------------|------------------|-----------------|
| 1               | Harvey           | Deitel          |
| 2               | Paul             | Deitel          |
| 3               | Tem              | Nieto           |
| 4               | Sean             | Santry          |

The **publishers** table (described in [Fig. 25.5](#)) consists of two columns representing each publisher's unique ID and name. [Figure 25.6](#) contains the data from the **publishers** table of the **books** database. The **titles** table (described in [Fig. 25.7](#)) consists of seven columns that maintain general information about each book in the database, including the ISBN, title, edition number, copyright year, publisher's ID number, name of a file containing an image of the book cover and price. The **publisherID** column is a **foreign key** a column in

this table that matches the primary key column in another table (i.e., `publisherID` in the `publishers` table). Foreign keys are specified when creating a table. The foreign key helps maintain the [Rule of Referential Integrity](#): Every foreign key value must appear as another table's primary key value. This enables the DBMS to determine whether the `publisherID` value for a particular book is valid. Foreign keys also allow related data in multiple tables to be selected from those tables for analytic purposes this is known as [joining](#) the data. There is a one-to-many relationship between a primary key and a corresponding foreign key (e.g., one publisher can publish many books). This means that a foreign key can appear many times in its own table, but can only appear once (as the primary key) in another table. [Figure 25.8](#) contains sample data from the `titles` table.

Figure 25.5. `publishers` table from `books`.

(This item is displayed on page 1193 in the print version)

| Column                     | Description                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------|
| <code>publisherID</code>   | The publisher's ID number in the database. This autoincremented integer is the table's primary key. |
| <code>publisherName</code> | The name of the publisher (a string).                                                               |

Figure 25.6. Data from the `publishers` table.

| 0130895601        | Advanced Java 2 Platform How to Program       | 1                           | 2002                   | 1                         | <code>advjhtp1.jpg</code> | 69.95              |

The `authorISBN` table (described in [Fig. 25.9](#)) consists of two columns that maintain each ISBN and the corresponding author's ID number. This table associates authors with their books. Both columns are foreign keys that represent the relationship between the tables `authors` and `titles`one row in table `authors` may be associated with many rows in table `titles`, and vice versa. [Figure 25.10](#) contains sample data from the `authorISBN` table of the `books` database. [*Note:* To save space, we have split the contents of this table into two columns, each containing the `authorID` and `isbn` columns.]

Figure 25.9. `authorISBN` table from `books`.

(This item is displayed on page 1195 in the print version)

| Column                | Description                                                              |
|-----------------------|--------------------------------------------------------------------------|
| <code>authorID</code> | The author's ID number, a foreign key to the <code>authors</code> table. |
| <code>isbn</code>     | The ISBN for a book, a foreign key to the <code>titles</code> table.     |

Figure 25.10. Sample data from the **authorISBN** table of **books**.

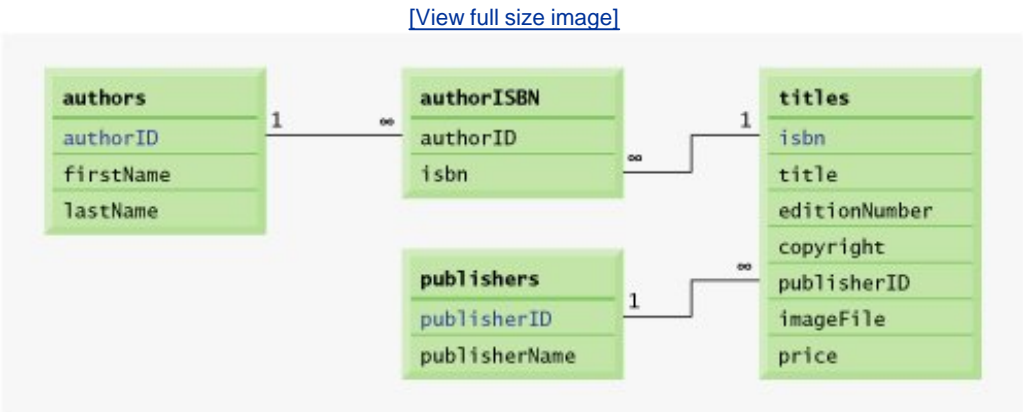

(This item is displayed on page 1195 in the print version)

| authorID | isbn       | authorID | isbn       |
|----------|------------|----------|------------|
| 1        | 0130895725 | 2        | 0139163050 |
| 2        | 0130895725 | 3        | 0130829293 |
| 2        | 0132261197 | 3        | 0130284173 |
| 2        | 0130895717 | 3        | 0130284181 |
| 2        | 0135289106 | 4        | 0130895601 |

[Figure 25.11](#) is an **entity-relationship (ER) diagram** for the **books** database. This diagram shows the tables in the database and the relationships among them. The first compartment in each box contains the table's name. The names in green are primary keys. A table's primary key uniquely identifies each row in the table. Every row must have a value in the primary key, and the value of the key must be unique in the table. This is known as the **Rule of Entity Integrity**.

Figure 25.11. Table relationships in **books**.

(This item is displayed on page 1196 in the print version)

### Common Programming Error 25.1

*Not providing a value for every column in a primary key breaks the Rule of Entity Integrity and causes the DBMS to report an error.*

### Common Programming Error 25.2

*Providing the same value for the primary key in multiple rows causes the DBMS to report an error.*

---

[Page 1195]

The lines connecting the tables in [Fig. 25.11](#) represent the relationships between the tables. Consider the line between the `publishers` and `titles` tables. On the `publishers` end of the line, there is a `1`, and on the `titles` end, there is an infinity symbol ( $\infty$ ), indicating a **one-to-many relationship** in which every publisher in the `publishers` table can have an arbitrary number of books in the `titles` table. Note that the relationship line links the `publisherID` column in the table `publishers` (i.e., its primary key) to the `publisherID` column in table `titles` (i.e., its foreign key). The `publisherID` column in the `titles` table is a foreign key.

---

[Page 1196]

### Common Programming Error 25.3

*Providing a foreign-key value that does not appear as a primary-key value in another table breaks the Rule of Referential Integrity and causes the DBMS to report an error.*

The line between the `authorISBN` and `authors` tables indicates that for each author in the `authors` table, there can be an arbitrary number of ISBNs for books written by that author in the `authorISBN` table. The `authorID` column in the `authorISBN` table is a foreign key matching the `authorID` column (the primary key) of the `authors` table. Note again that the line between the tables links the foreign key in table `authorISBN` to the corresponding primary key in table `authors`. The `authorISBN` table associates rows in the `titles` and `authors` tables.

Finally, the line between the `titles` and `authorISBN` tables illustrates a one-to-many relationship; a title can be written by any number of authors. In fact, the sole purpose of the `authorISBN` table is to provide a many-to-many relationship between the `authors` and `titles` tables; an author can write any number of books and a book can have any number of authors.

## 25.4. SQL

We now provide an overview of SQL in the context of our `books` sample database. You will be able to use the SQL discussed here in the examples later in the chapter.

The SQL keywords listed in [Fig. 25.12](#) are discussed in the context of complete SQL queries and statements in the next several subsections. Other SQL keywords are beyond the scope of this text. To learn other keywords, you could refer to the SQL reference guide supplied by the vendor of the RDBMS you are using. [*Note:* For more information on SQL, please refer to the Internet and Web resources in [Section 25.12](#) and the Recommended Readings at the end of this chapter.]

Figure 25.12. SQL query keywords.

| SQL keyword             | Description                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>SELECT</code>     | Retrieves data from one or more tables.                                                                                         |
| <code>FROM</code>       | Tables involved in the query. Required in every <code>SELECT</code> .                                                           |
| <code>WHERE</code>      | Criteria for selection that determine the rows to be retrieved, deleted or updated. Optional in a SQL query or a SQL statement. |
| <code>GROUP BY</code>   | Criteria for grouping rows. Optional in a <code>SELECT</code> query.                                                            |
| <code>ORDER BY</code>   | Criteria for ordering rows. Optional in a <code>SELECT</code> query.                                                            |
| <code>INNER JOIN</code> | Merge rows from multiple tables.                                                                                                |
| <code>INSERT</code>     | Insert rows into a specified table.                                                                                             |
| <code>UPDATE</code>     | Update rows in a specified table.                                                                                               |
| <code>DELETE</code>     | Delete rows from a specified table.                                                                                             |

### 25.4.1. Basic `SELECT` Query

Let us consider several SQL queries that extract information from database `books`. A SQL query "selects" rows and columns from one or more tables in a database. Such selections are performed by queries with the `SELECT` keyword. The basic form of a `SELECT` query is

```
SELECT * FROM tableName
```

in which the asterisk (\*) indicates that all columns from the *tableName* table should be retrieved. For example, to retrieve all the data in the `authors` table, use

```
SELECT * FROM authors
```

Most programs do not require all the data in a table. To retrieve only specific columns from a table, replace the asterisk (\*) with a comma-separated list of the column names. For example, to retrieve only the columns `authorID` and `lastName` for all rows in the `authors` table, use the query

```
SELECT authorID, lastName FROM authors
```

This query returns the data listed in [Fig. 25.13](#).

Figure 25.13.  
Sample `authorID`  
and `lastName`  
data from the  
`authors` table.

(This item is displayed on  
page 1198 in the print  
version)

| authorID | lastName |
|----------|----------|
| 1        | Deitel   |
| 2        | Deitel   |
| 3        | Nieto    |
| 4        | Santry   |

## Software Engineering Observation 25.2

*For most queries, the asterisk (\*) should not be used to specify column names. In general, programmers process results by knowing in advance the order of the columns in the result for example selecting `authorID` and `lastName` from table `authors` ensures that the columns will appear in the result with `authorID` as the first column and `lastName` as the second column. Programs typically process result columns by specifying the column number in the result (starting from number 1 for the first column). Selecting columns by name also avoids returning unneeded columns and protects against changes in the actual order of the columns in the table(s).*

## Common Programming Error 25.4

*If a programmer assumes that the columns are always returned in the same order from a query that uses the asterisk (\*), the program may process the result incorrectly. If the column order in the table(s) changes or if additional columns are added at a later time, the order of the columns in the result would change accordingly.*

## 25.4.2. WHERE Clause

In most cases, it is necessary to locate rows in a database that satisfy certain **selection criteria**. Only rows that satisfy the selection criteria (formally called **predicates**) are selected. SQL uses the optional **WHERE clause** in a query to specify the selection criteria for the query. The basic form of a query with selection criteria is

```
SELECT columnName1, columnName2, ... FROM tableName WHERE criteria
```

For example, to select the **title**, **editionNumber** and **copyright** columns from table **titles** for which the **copyright** date is greater than 2002, use the query

```
SELECT title, editionNumber, copyright
FROM titles
WHERE copyright > 2002
```

Figure 25.14 shows the result of the preceding query. The **WHERE** clause criteria can contain the operators **<**, **>**, **<=**, **>=**, **=**, **<>** and **LIKE**. Operator **LIKE** is used for **pattern matching** with wildcard characters **percent (%)** and **underscore (\_)**. Pattern matching allows SQL to search for strings that match a given pattern.

Figure 25.14. Sampling of titles with copyrights after 2002 from table **titles**.

| title                                      | editionNumber | copyright |
|--------------------------------------------|---------------|-----------|
| The Complete C++ Training Course           | 4             | 2003      |
| Java How to Program                        | 5             | 2003      |
| C How to Program                           | 4             | 2004      |
| Internet and World Wide Web How to Program | 3             | 2004      |
| Java How to Program                        | 6             | 2005      |
| C# How to Program                          | 1             | 2003      |

A pattern that contains a percent character (%) searches for strings that have zero or more characters at the percent character's position in the pattern. For example, the following query locates the rows of all the authors whose last name starts with the letter D:

```
SELECT authorID, firstName, lastName
FROM authors
WHERE lastName LIKE 'D%'
```

The preceding query selects the two rows shown in [Fig. 25.15](#), because two of the four authors in our database have a last name starting with the letter **D** (followed by zero or more characters). The **%** in the **WHERE** clause's **LIKE** pattern indicates that any number of characters can appear after the letter **D** in the **lastName** column. Note that the pattern string is surrounded by single-quote characters.

Figure 25.15. Authors whose last name starts with **D** from the **authors** table.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |

### Portability Tip 25.1

*See the documentation for your database system to determine whether SQL is case sensitive on your system and to determine the syntax for SQL keywords (i.e., should they be all uppercase letters, all lowercase letters or some combination of the two?).*

### Portability Tip 25.2

*Read your database system's documentation carefully to determine whether your system supports the **LIKE** operator.*

### Portability Tip 25.3

*Some databases use the **\*** character in place of the **%** character in a pattern.*

An underscore ( `_` ) in the pattern string indicates a single wildcard character at that position in the pattern. For example, the following query locates the rows of all the authors whose last names start with any character (specified by `_`), followed by the letter `i`, followed by any number of additional characters (specified by `%`):

```
SELECT authorID, firstName, lastName
FROM authors
WHERE lastName LIKE '_i%'
```

The preceding query produces the row shown in [Fig. 25.16](#), because only one author in our database has a last name that contains the letter `i` as its second letter.

Figure 25.16. The only author from the `authors` table whose last name contains `i` as the second letter.

(This item is displayed on page 1200 in the print version)

| authorID | firstName | lastName |
|----------|-----------|----------|
| 3        | Tem       | Nieto    |

Portability Tip 25.4

*Some database systems use the `?` character in place of the `_` character in a pattern.*

25.4.3. ORDER BY Clause

The rows in the result of a query can be sorted into ascending or descending order by using the optional `ORDER BY clause`. The basic form of a query with an `ORDER BY` clause is

```
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column ASC
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column DESC
```

where `ASC` specifies ascending order (lowest to highest), `DESC` specifies descending order (highest to lowest) and `column` specifies the column on which the sort is based. For example, to obtain the list of authors in ascending order by last name ([Fig. 25.17](#)), use the query

```
SELECT authorID, firstName, lastName
FROM authors
ORDER BY lastName ASC
```

Figure 25.17. Sample data from table **authors** in ascending order by **lastName**.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Tem       | Nieto    |
| 4        | Sean      | Santry   |

Note that the default sorting order is ascending, so **ASC** is optional. To obtain the same list of authors in descending order by last name ([Fig. 25.18](#)), use the query

```
SELECT authorID, firstName, lastName
FROM authors
ORDER BY lastName DESC
```

Figure 25.18. Sample data from table **authors** in descending order by **lastName**.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 4        | Sean      | Santry   |
| 3        | Tem       | Nieto    |
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |

Multiple columns can be used for sorting with an **ORDER BY** clause of the form

```
ORDER BY column1 sortingOrder, column2 sortingOrder, ...
```

where *sortingOrder* is either **ASC** or **DESC**. Note that the *sortingOrder* does not have to be identical for each

column. The query

```
SELECT authorID, firstName, lastName
FROM authors
ORDER BY lastName, firstName
```

sorts all the rows in ascending order by last name, then by first name. If any rows have the same last name value, they are returned sorted by first name ([Fig. 25.19](#)).

Figure 25.19. Sample data from **authors** in ascending order by **lastName** and **firstName**.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Tem       | Nieto    |
| 4        | Sean      | Santry   |

The **WHERE** and **ORDER BY** clauses can be combined in one query. For example, the query

```
SELECT isbn, title, editionNumber, copyright, price
FROM titles
WHERE title LIKE '%How to Program'
ORDER BY title ASC
```

returns the **isbn**, **title**, **editionNumber**, **copyright** and **price** of each book in the **titles** table that has a **title** ending with "How to Program" and sorts them in ascending order by **title**. A portion of the query results are shown in [Fig. 25.20](#).

Figure 25.20. Sampling of books from table **titles** whose titles end with **How to Program** in ascending order by **title**.

(This item is displayed on page 1202 in the print version)

#### 25.4.4. Merging Data from Multiple Tables: INNER JOIN

Database designers often split related data into separate tables to ensure that a database does not store data redundantly. For example, the `books` database has tables `authors` and `titles`. We use an `authorISBN` table to store the relationship data between authors and their corresponding titles. If we did not separate this information into individual tables, we would need to include author information with each entry in the `titles` table. This would result in the database storing duplicate author information for authors who wrote multiple books. Often, it is necessary to merge data from multiple tables into a single result. Referred to as joining the tables, this is specified by an `INNER JOIN` operator in the query. An `INNER JOIN` merges rows from two tables by matching values in columns that are common to the tables. The basic form of an `INNER JOIN` is:

```
SELECT columnName1, columnName2,...
FROM table1
INNER JOIN table2
ON table1. columnName = table2. columnName
```

---

[Page 1202]

The `ON clause` of the `INNER JOIN` specifies the columns from each table that are compared to determine which rows are merged. For example, the following query produces a list of authors accompanied by the ISBNs for books written by each author:

```
SELECT firstName, lastName, isbn
FROM authors
INNER JOIN authorISBN
ON authors.authorID = authorISBN.authorID
ORDER BY lastName, firstName
```

The query merges data from the `firstName` and `lastName` columns from table `authors` with the `isbn` column from table `authorISBN`, sorting the result in ascending order by `lastName` and `firstName`. Note the use of the syntax `tableName. columnName` in the `ON clause`. This syntax (called a `qualified name`) specifies the columns from each table that should be compared to join the tables. The "`tableName:`" syntax is required if the columns have the same name in both tables. The same syntax can be used in any query to distinguish columns in different tables that have the same name. In some systems, table names qualified with the database name can be used to perform cross-database queries.

## Software Engineering Observation 25.3

*If a SQL statement includes columns from multiple tables that have the same name, the statement must precede those column names with their table names and a dot (e.g., `authors.authorID`).*

## Common Programming Error 25.5

*In a query, failure to qualify names for columns that have the same name in two or more tables is an error.*

---

[Page 1203]

As always, the query can contain an `ORDER BY` clause. [Figure 25.21](#) depicts a portion of the results of the preceding query, ordered by `lastName` and `firstName`. [*Note:* To save space, we split the result of the query into two columns, each containing the `firstName`, `lastName` and `isbn` columns.]

Figure 25.21. Sampling of authors and ISBNs for the books they have written in ascending order by `lastName` and `firstName`.

| <code>firstName</code> | <code>lastName</code> | <code>isbn</code> | <code>firstName</code> | <code>lastName</code> | <code>isbn</code> |
|------------------------|-----------------------|-------------------|------------------------|-----------------------|-------------------|
| Harvey                 | Deitel                | 0130895601        | Paul                   | Deitel                | 0130895717        |
| Harvey                 | Deitel                | 0130284181        | Paul                   | Deitel                | 0132261197        |
| Harvey                 | Deitel                | 0134569555        | Paul                   | Deitel                | 0130895725        |
| Harvey                 | Deitel                | 0139163050        | Paul                   | Deitel                | 0130829293        |
| Harvey                 | Deitel                | 0135289106        | Paul                   | Deitel                | 0134569555        |
| Harvey                 | Deitel                | 0130895717        | Paul                   | Deitel                | 0130829277        |

### 25.4.5. `INSERT` Statement

The `INSERT` statement inserts a row into a table. The basic form of this statement is

```
INSERT INTO tableName (columnName1, columnName2, ..., columnNameN)
VALUES (value1, value2, ..., valueN)
```

where *tableName* is the table in which to insert the row. The *tableName* is followed by a comma-separated list of column names in parentheses (this list is not required if the **INSERT** operation specifies a value for every column of the table in the correct order). The list of column names is followed by the SQL keyword **VALUES** and a comma-separated list of values in parentheses. The values specified here must match the columns specified after the table name in both order and type (se.g., if *columnName1* is supposed to be the **firstName** column, then *value1* should be a string in single quotes representing the first name). Always explicitly list the columns when inserting rows. If the order of the columns changes in the table, using only **VALUES** may cause an error. The **INSERT** statement

```
INSERT INTO authors (firstName, lastName)
VALUES ('Sue', 'Smith')
```

inserts a row into the **authors** table. The statement indicates that values are provided for the **firstName** and **lastName** columns. The corresponding values are 'Sue' and 'Smith'. We do not specify an **authorID** in this example because **authorID** is an **autoincremented column** in the **authors** table. For every row added to this table, MySQL assigns a unique **authorID** value that is the next value in the autoincremented sequence (i.e., 1, 2, 3 and so on). In this case, Sue Smith would be assigned **authorID** number 5. [Figure 25.22](#) shows the **authors** table after the **INSERT** operation. [*Note:* Not every database management system supports autoincremented columns. Check the documentation for your DBMS for alternatives to autoincremented columns.]

Figure 25.22. Sample data from table **Authors** after an **INSERT** operation.

| <b>authorID</b> | <b>firstName</b> | <b>lastName</b> |
|-----------------|------------------|-----------------|
| 1               | Harvey           | Deitel          |
| 2               | Paul             | Deitel          |
| 3               | Tem              | Nieto           |
| 4               | Sean             | Santry          |
| 5               | Sue              | Smith           |

### Common Programming Error 25.6

*It is an error to specify a value for an autoincrement column.*

## Common Programming Error 25.7

*SQL uses the single-quote (') character as a delimiter for strings. To specify a string containing a single quote (e.g., O'Malley) in a SQL statement, the string must have two single quotes in the position where the single-quote character appears in the string (e.g., 'O''Malley'). The first of the two single-quote characters acts as an escape character for the second. Not escaping singlequote characters in a string that is part of a SQL statement is a SQL syntax error.*

### 25.4.6. UPDATE Statement

An **UPDATE** statement modifies data in a table. The basic form of the **UPDATE** statement is

```
UPDATE tableName
SET columnName1 = value1, columnName2 = value2, ..., columnNameN = valueN
WHERE criteria
```

where *tableName* is the table to update. The *tableName* is followed by keyword **SET** and a comma-separated list of column name-value pairs in the format *columnName = value*. The optional **WHERE** clause provides criteria that determine which rows to update. Though not required, the **WHERE** clause is typically used, unless a change is to be made to every row. The **UPDATE** statement

```
UPDATE authors
SET lastName = 'Jones'
WHERE lastName = 'Smith' AND firstName = 'Sue'
```

updates a row in the **authors** table. The statement indicates that **lastName** will be assigned the value **Jones** for the row in which **lastName** is equal to **Smith** and **firstName** is equal to **Sue**. [Note: If there are multiple rows with the first name "Sue" and the last name "Smith," this statement will modify all such rows to have the last name "Jones."] If we know the **authorID** in advance of the **UPDATE** operation (possibly because we searched for it previously), the **WHERE** clause could be simplified as follows:

---

```
WHERE AuthorID = 5
```

[Figure 25.23](#) shows the **authors** table after the **UPDATE** operation has taken place.

Figure 25.23. Sample data from table **authors** after an **UPDATE** operation.

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Tem       | Nieto    |
| 4        | Sean      | Santry   |
| 5        | Sue       | Jones    |

## 25.4.7. DELETE Statement

A SQL **DELETE** statement removes rows from a table. The basic form of a **DELETE** statement is

```
DELETE FROM tableName WHERE criteria
```

where *tableName* is the table from which to delete. The optional **WHERE** clause specifies the criteria used to determine which rows to delete. The **DELETE** statement

```
DELETE FROM authors
WHERE lastName = 'Jones' AND firstName = 'Sue'
```

deletes the row for Sue Jones in the **authors** table. If we know the **authorID** in advance of the **DELETE** operation, the **WHERE** clause can be simplified as follows:

```
WHERE authorID = 5
```

## 25.5. Instructions to install MySQL and MySQL Connector/J

The CD that accompanies this book includes MySQL 4.0.20an open-source database management system. MySQL executes on many platforms, including Windows, Solaris, Linux, and Macintosh. Complete information about MySQL is available from

[www.mysql.com/products/mysql/](http://www.mysql.com/products/mysql/)

To install MySQL:

1. Insert the CD into the CD drive (the `D:` drive on our system), and change directories to `D:\software\MySQL\mysql-4.0.20c-win`.
2. Double click `SETUP.EXE` to start the MySQL installer. Follow the instructions to install MySQL in the `C:\mysql` directory, which is the default directory.

Instructions for installing MySQL can also be found in Chapter 2 of the *MySQL Manual* at [dev.mysql.com/doc/mysql/en/index.html](http://dev.mysql.com/doc/mysql/en/index.html).

To use MySQL with JDBC, you also need to install MySQL Connector/Ja JDBC driver that allows programs to access MySQL databases via JDBC. MySQL Connector/J is on the CD that accompanies this book and can also be downloaded from

[www.mysql.com/products/connector/j/](http://www.mysql.com/products/connector/j/)

At the time of this writing, the current stable release of MySQL Connector/J is 3.0.14. To install MySQL Connector/J:

1. Copy `mysql-connector-java-3.0.14-production.zip` to your hard disk.
2. Open `mysql-connector-java-3.0.14-production.zip` with a file extractor, such as WinZip, which can be downloaded from [www.winzip.com](http://www.winzip.com). Extract its content to the `C:\` drive. This will create a directory named `mysql-connector-java-3.0.14-production`. The documentation for MySQL Connector/J is in `connector-j-en.pdf` in the `docs` subdirectory of `mysql-connector-java-3.0.14-production`, or you can view it online at [dev.mysql.com/doc/connector/j/en/index.html](http://dev.mysql.com/doc/connector/j/en/index.html).

## 25.6. Instructions on Setting MySQL User Account

For the examples in the book to execute correctly, you need to set up a user account that allows users to create, delete and modify a database. After MySQL is installed, follow the steps below to set up a user account (these steps assume MySQL is installed in its default installation directory):

1. Open a **Command Prompt** and start the database server by executing the `C:\mysql\bin\mysqld script`.
2. Open another **Command Prompt** and change to the `C:\mysql\bin` directory. To start the MySQL monitor so you can set up a user account, execute the command

```
C:\mysql\bin>mysql -h localhost -u root
```

---

[Page 1207]

3. For our examples, we set up a user account on the local computer (`localhost`) with the username set "`jhtp6`" and the password "`jhtp6`". To do this, execute the following commands in the **Command Prompt** created in Step 2:

```
mysql> USE mysql;
mysql> INSERT INTO user SET Host='localhost', User='jhtp6',
 Password=PASSWORD('jhtp6'), Select_priv='Y',
 Insert_priv='Y', Update_priv='Y', Delete_priv='Y',
 Create_priv='Y', Drop_priv='Y', References_priv='Y',
 Execute_priv='Y';
mysql> FLUSH PRIVILEGES;
mysql> exit;
```

## 25.7. Creating Database books in MySQL

For each MySQL database we discuss in this book, we provide a SQL script that will set up the database and its tables. These scripts can be executed with a command-line tool called `mysql` that is part of the MySQL installation. In the examples directory for this chapter on the CD that accompanies this book, you will find the SQL script `books.sql`.

To create the `books` database:

1. Open a **Command Prompt** and change to the `C:\mysql\bin` directory. [*Note:* If you installed MySQL on a directory other than `C:\mysql`, replace `C:\mysql` with your MySQL installation directory.]
2. Start the database server by executing the command

```
C:\mysql\bin>mysqld
```

3. Copy the SQL script `books.sql` to the `C:\mysql\bin` directory. [*Note:* If you installed MySQL on a directory other than `C:\mysql`, replace `C:\mysql` with your MySQL installation directory.]
4. Open a new **Command Prompt** and change to the `C:\mysql\bin` directory. [*Note:* If you installed MySQL on a directory other than `C:\mysql`, replace `C:\mysql` with your MySQL installation directory.]
5. Create the books database by executing the command

```
C:\mysql\bin>mysql -h localhost -u jhttp6 -p < books.sql
```

When the above command is executed, you are prompted for entering the password, which is `jhttp6`. After completing this task, a new directory named `books` will be created in the `C:\mysql\data` directory. This new directory contains the `books` database. You are now ready to proceed to the first JDBC example.

## 25.8. Manipulating Databases with JDBC

In this section, we present two examples. The first example introduces how to connect to a database and query the database. The second example demonstrates how to display the result of the query in a `JTable`.

### 25.8.1. Connecting to and Querying a Database

The example of [Fig. 25.25](#) performs a simple query on the `books` database that retrieves the entire `authors` table and displays the data. The program illustrates connecting to the database, querying the database and processing the result. The following discussion presents the key JDBC aspects of the program. [Note: [Section 25.5](#) demonstrates how to start the MySQL server, how to prepare the MySQL database and how to create the `books` database. The steps in [Section 25.5](#) must be performed before executing the program of [Fig. 25.25](#).]

Figure 25.25. Displaying the `authors` table from the `books` database.

(This item is displayed on pages 1208 - 1209 in the print version)

```
1 // Fig. 25.25: DisplayAuthors.java
2 // Displaying the contents of the authors table.
3 import java.sql.Connection;
4 import java.sql.Statement;
5 import java.sql.DriverManager;
6 import java.sql.ResultSet;
7 import java.sql.ResultSetMetaData;
8 import java.sql.SQLException;
9
10 public class DisplayAuthors
11 {
12 // JDBC driver name and database URL
13 static final String JDBC_DRIVER = "com.mysql.jdbc.Driver";
14 static final String DATABASE_URL = "jdbc:mysql://localhost/books";
15
16 // launch the application
17 public static void main(String args[])
18 {
19 Connection connection = null; // manages connection
20 Statement statement = null; // query statement
21
22 // connect to database books and query database
23 try
24 {
25 Class.forName(JDBC_DRIVER); // load database driver class
26
27 // establish connection to database
28 connection =
29 DriverManager.getConnection(DATABASE_URL, "jhttp6", "jhttp6");
30
31 }
32 }
33 }
```

```

31 // create Statement for querying database
32 statement = connection.createStatement();
33
34 // query database
35 ResultSet resultSet = statement.executeQuery(
36 "SELECT authorID, firstName, lastName FROM authors");
37
38 // process query results
39 ResultSetMetaData metaData = resultSet.getMetaData();
40 int numberOfColumns = metaData.getColumnCount();
41 System.out.println("Authors Table of Books Database:");
42
43 for (int i = 1; i <= numberOfColumns; i++)
44 System.out.printf("%-8s\t", metaData.getColumnName(i));
45 System.out.println();
46
47 while (resultSet.next())
48 {
49 for (int i = 1; i <= numberOfColumns; i++)
50 System.out.printf("%-8s\t", resultSet.getObject(i));
51 System.out.println();
52 } // end while
53 } // end try
54 catch (SQLException sqlException)
55 {
56 sqlException.printStackTrace();
57 System.exit(1);
58 } // end catch
59 catch (ClassNotFoundException classNotFound)
60 {
61 classNotFound.printStackTrace();
62 System.exit(1);
63 } // end catch
64 finally // ensure statement and connection are closed properly
65 {
66 try
67 {
68 statement.close();
69 connection.close();
70 } // end try
71 catch (Exception exception)
72 {
73 exception.printStackTrace();
74 System.exit(1);
75 } // end catch
76 } // end finally
77 } // end main
78 } // end class DisplayAuthors

```

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Tem       | Nieto    |
| 4        | Sean      | Santry   |

Lines 38 import the JDBC interfaces and classes from package `java.sql` used in this program. Line 13 declares a `String` constant that contains the MySQL JDBC driver's class name. The program will use this value to load the proper driver into memory. Line 14 declares a string constant for the database URL. This identifies the name of the database to connect to, as well as information about the protocol used by the JDBC driver (discussed shortly). Method `main` (lines 1776) connects to the books database, queries the database, displays the result of the query and closes the database connection.

[Page 1210]

The program must load the database driver before connecting to the database. Line 25 uses `static` method `forName` of class `Class` to load the class for the database driver. This line throws a checked exception of type `java.lang.ClassNotFoundException` if the class loader cannot locate the driver class. To avoid this exception, you need to include the `mysql-connector-java-3.0.14-production-bin.jar` (in the `C:\mysql-connector-java-3.0.14-production` directory) in your program's classpath when you execute the program, as in:

[\[View full width\]](#)

```
java -classpath c:\mysql-connector-java-3.0.14-production\mysql-connector-java-3.0
14-production-bin.jar;. DisplayAuthors
```

In the above command, notice the period (.) before `DisplayAuthors`. If this period is missing, the JVM will not find the `DisplayAuthors` class file. You may also copy the `mysql-connector-java-3.0.14-production-bin.jar` file to the JRE's `lib\ext` directory, e.g., `C:\Program Files\Java\jdk1.5.0\jre\lib\ext`. After doing so, you could run the application simply using the command `java DisplayAuthors`.

JDBC supports four categories of drivers: [JDBC-to-ODBC bridge driver](#) (Type 1), [Native-API, partly Java driver](#) (Type 2), [Pure Java client to server driver](#) (Type 3) and [Pure Java driver](#) (Type 4). A description of each driver type is shown in [Fig. 25.26](#). The MySQL driver `com.mysql.jdbc.Driver` is a Type-4 driver.

Figure 25.26. JDBC driver types.

| Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | The JDBC-to-ODBC bridge driver connects Java programs to Microsoft ODBC (Open Database Connectivity) data sources. The Java 2 Software Development Kit from Sun Microsystems, Inc. includes the JDBC-to-ODBC Bridge driver ( <code>sun.jdbc.odbc.JdbcOdbcDriver</code> ). This driver typically requires the ODBC driver on the client computer and normally requires configuration of ODBC data sources. The Bridge driver was introduced primarily for development purposes, before other types of drivers were available, and should not be used for production applications. |
| 2    | Native-API, partly Java drivers enable JDBC programs to use database-specific APIs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      | (normally written in C or C++) that allow client programs to access databases via the <a href="#">Java Native Interface (JNI)</a> . JNI is a bridge between a JVM and code written and compiled in a platform-specific language such as C or C++. Such code is known as <a href="#">native code</a> . JNI enables Java applications to interact with native code. A Type 2 driver translates JDBC into database-specific calls. Type 2 drivers were introduced for reasons similar to the Type 1 ODBC bridge driver. |
| 3    | Pure Java client to server drivers take JDBC requests and translate them into a network protocol that is not database specific. These requests are sent to a server, which translates the database requests into a database-specific protocol.                                                                                                                                                                                                                                                                       |
| 4    | Pure Java drivers implement database-specific network protocols, so that Java programs can connect directly to a database.                                                                                                                                                                                                                                                                                                                                                                                           |

[Page 1211]

## Software Engineering Observation 25.4

*Most major database vendors provide their own JDBC database drivers, and many third-party vendors provide JDBC drivers as well. For more information on JDBC drivers, visit the Sun Microsystems JDBC Web site, [servlet.java.sun.com/products/jdbc/drivers](http://servlet.java.sun.com/products/jdbc/drivers).*

## Software Engineering Observation 25.5

*On the Microsoft Windows platform, most databases support access via Open Database Connectivity (ODBC). ODBC is a technology developed by Microsoft to allow generic access to disparate database systems on the Windows platform (and some UNIX platforms). The JDBC-to-ODBC Bridge allows any Java program to access any ODBC data source. The driver is class `JdbcOdbcDriver` in package `sun.jdbc.odbc`.*

Lines 2829 of [Fig. 25.25](#) creates a `Connection` object (package `java.sql`) referenced by `connection`. An object that implements interface `Connection` manages the connection between the Java program and the database. `Connection` objects enable programs to create SQL statements that access databases. The program initializes `Connection` with the result of a call to `static` method `getConnection` of class `DriverManager` (package `java.sql`), which attempts to connect to the database specified by its URL. Method `getConnection` takes three arguments: a `String` that specifies the database URL, a `String` that specifies the username and a `String` that specifies the password. The username and password are set in [Section 25.6](#). If you used different username and password, you need to replace the username (second argument) and password (third argument) passed to method `getConnection` in line 29. The URL locates the database (possibly on a network or in the local file system of the computer). The URL `jdbc:mysql://localhost/books` specifies the protocol for communication (`jdbc`), the `subprotocol` for communication (`mysql`) and the location of the database (`//localhost/books`, where `localhost` is the name of the MySQL server host and `books` is the database name). The subprotocol `mysql` indicates that the program uses a MySQL-specific subprotocol to connect to the MySQL database. If the `DriverManager` cannot connect to the database, method `getConnection` throws a `SQLException` (package `java.sql`). [Figure 25.27](#)

lists the JDBC driver names and database URL formats of several popular RDBMSs.

Figure 25.27. Popular JDBC driver names and database URL.

| RDBMS  | JDBC driver name                             | Database URL format                                                   |
|--------|----------------------------------------------|-----------------------------------------------------------------------|
| MySQL  | <code>com.mysql.jdbc.Driver</code>           | <code>jdbc:mysql://hostname/databaseName</code>                       |
| ORACLE | <code>oracle.jdbc.driver.OracleDriver</code> | <code>jdbc:oracle:thin:@hostname.port<br/>Number: databaseName</code> |
| DB2    | <code>COM.ibm.db2.jdbc.net.DB2Driver</code>  | <code>jdbc:db2:hostname.portnumber/<br/>databaseName</code>           |
| Sybase | <code>com.sybase.jdbc.SybDriver</code>       | <code>jdbc:sybase:Tds:hostname.<br/>portnumber/ databaseName</code>   |

Software Engineering Observation 25.6

Most database management systems require the user to log in before accessing the database contents. `DriverManager` method `getConnection` is overloaded with versions that enable the program to supply the user name and password to gain access.

Line 32 invokes `Connection` method `createStatement` to obtain an object that implements interface `Statement` (package `java.sql`). The program uses the `Statement` object to submit SQL to the database.

Lines 3536 use the `Statement` object's `executeQuery` method to submit a query that selects all the author information from table `authors`. This method returns an object that implements interface `ResultSet` and contains the result of the query. The `ResultSet` methods enable the program to manipulate the query result.

Lines 3952 process the `ResultSet`. Line 39 obtains the `metadata` for the `ResultSet` as a `ResultSetMetaData` (package `java.sql`) object. The metadata describes the `ResultSet`'s contents. Programs can use metadata programmatically to obtain information about the `ResultSet`'s column names and types. Line 40 uses `ResultSetMetaData` method `getColumnCount` to retrieve the number of columns in the `ResultSet`. Lines 4243 display the column names.

Software Engineering Observation 25.7

Metadata enables programs to process `ResultSet` contents dynamically when detailed information about the `ResultSet` is not known in advance.

Lines 4752 display the data in each `ResultSet` row. Before processing the `ResultSet`, the program positions

the `ResultSet` cursor to the first row in the `ResultSet` with method `next` (line 47). The cursor points to the current row. Method `next` returns `boolean` value `true` if it is able to position to the next row; otherwise the method returns `false`.

## Common Programming Error 25.8

*Initially, a `ResultSet` cursor is positioned before the first row. Attempting to access a `ResultSet`'s contents before positioning the `ResultSet` cursor to the first row with method `next` causes a `SQLException`.*

If there are rows in the `ResultSet`, line 50 extracts the contents of one column in the current row. When processing a `ResultSet`, it is possible to extract each column of the `ResultSet` as a specific Java type. In fact, `ResultSetMetaData` method `getColumnType` returns a constant integer from class `Types` (package `java.sql`) indicating the type of a specified column. Programs can use these values in a `switch` statement to invoke `ResultSet` methods that return the column values as appropriate Java types. If the type of a column is `Types.INT`, `ResultSet` method `getInt` returns the column value as an `int`. `ResultSet` `get` methods typically receive as an argument either a *column number* (as an `int`) or a *column name* (as a `String`) indicating which column's value to obtain. Visit

[java.sun.com/j2se/5.0/docs/guide/jdbc/getstart/GettingStartedTOC.fm.html](http://java.sun.com/j2se/5.0/docs/guide/jdbc/getstart/GettingStartedTOC.fm.html)

for detailed mappings of SQL data types to Java types and to determine the appropriate `ResultSet` method to call for each SQL data type.

---

[Page 1213]

## Performance Tip 25.1

*If a query specifies the exact columns to select from the database, the `ResultSet` contains the columns in the specified order. In this case, using the column number to obtain the column's value is more efficient than using the column name. The column number provides direct access to the specified column. Using the column name requires a linear search of the column names to locate the appropriate column.*

For simplicity, this example treats each value as an `Object`. The program retrieves each column value with `ResultSet` method `getObject` (line 50) and prints the `String` representation of the `Object`. Note that, unlike array indices, which start at 0, `ResultSet` column numbers start at 1. The `finally` block (lines 64-76) closes the `Statement` (line 68) and the database `Connection` (line 69).

## Common Programming Error 25.9

*Specifying column number 0 when obtaining values from a `ResultSet` causes a `SQLException`.*

## Common Programming Error 25.10

*Attempting to manipulate a `ResultSet` after closing the `Statement` that created the `ResultSet` causes a `SQLException`. The program discards the `ResultSet` when the corresponding `Statement` is closed.*

## Software Engineering Observation 25.8

*Each `Statement` object can open only one `ResultSet` object at a time. When a `Statement` returns a new `ResultSet`, the `Statement` closes the prior `ResultSet`. To use multiple `ResultSets` in parallel, separate `Statement` objects must return the `ResultSets`.*

### 25.8.2. Querying the `books` Database

The next example ([Fig. 25.28](#) and [Fig. 25.31](#)) allows the user to enter any query into the program. The example displays the result of a query in a `JTable`, using a `TableModel` object to provide the `ResultSet` data to the `JTable`. Class `ResultSetTableModel` ([Fig. 25.28](#)) performs the connection to the database and maintains the `ResultSet`. Class `DisplayQueryResults` ([Fig. 25.31](#)) creates the GUI and specifies an instance of class `ResultSetTableModel` to provide data for the `JTable`.

Figure 25.28. `ResultSetTableModel` enables a `JTable` to display the contents of a `ResultSet`.

(This item is displayed on pages 1214 - 1217 in the print version)

188 } // end finally
189 } // end method disconnectFromDatabase
190 } // end class ResultSetTableModel

```

Class `ResultSetTableModel` ([Fig. 25.28](#)) extends class `AbstractTableModel` (package `javax.swing.table`),

which implements interface `TableModel`. Class `ResultSetTableModel` overrides `TableModel` methods `getColumnClass`, `getColumnCount`, `getColumnName`, `getRowCount` and `getValueAt`. The default implementations of `TableModel` methods `isCellEditable` and `setValueAt` (provided by `AbstractTableModel`) are not overridden, because this example does not support editing the `JTable` cells. The default implementations of `TableModel` methods `addTableModelListener` and `removeTableModelListener` (provided by `AbstractTableModel`) are not overridden, because the implementations of these methods in `AbstractTableModel` properly add and remove event listeners.

The `ResultSetTableModel` constructor (lines 3050) accepts five `String` arguments: the driver class name, the URL of the database, the username, the password and the default query to perform. The constructor throws any exceptions that occur in its body back to the application that created the `ResultSetTableModel` object, so that the application can determine how to handle the exception (e.g., report an error and terminate the application). Line 35 loads the database driver. Line 38 establishes a connection to the database. Lines 41-43 invoke `Connection` method `createStatement` to create a `Statement` object. This example uses a version of method `createStatement` that takes two arguments: the `result set type` and the `result set concurrency`. The result set type ([Fig. 25.29](#)) specifies whether the `ResultSet`'s cursor is able to scroll in both directions or forward only and whether the `ResultSet` is sensitive to changes. `ResultSet`s that are sensitive to changes reflect those changes immediately after they are made with methods of interface `ResultSet`. If a `ResultSet` is insensitive to changes, the query that produced the `ResultSet` must be executed again to reflect any changes made. The result set concurrency ([Fig. 25.30](#)) specifies whether the `ResultSet` can be updated with `ResultSet`'s update methods. This example uses a `ResultSet` that is scrollable, insensitive to changes and read only. Line 49 invokes `ResultSetTableModel` method `setQuery` (lines 1481-67) to perform the default query.

---

[Page 1217]

---

[Page 1218]

## Portability Tip 25.5

*Some JDBC drivers do not support scrollable `ResultSet`s. In such cases, the driver typically returns a `ResultSet` in which the cursor can move only forward. For more information, see your database driver documentation.*

## Portability Tip 25.6

*Some JDBC drivers do not support updatable `ResultSet`s. In such cases, the driver typically returns a read-only `ResultSet`. For more information, see your database driver documentation.*

## Common Programming Error 25.11

*Attempting to update a `ResultSet` when the database driver does not support updatable `ResultSet`s causes `SQLException`s.*

Figure 25.29. `ResultSet` constants for specifying `ResultSet` type.

| ResultSet static type constant       | Description                                                                                                                                                                                                                                                                      |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TYPE_FORWARD_ONLY</code>       |                                                                                                                                                                                                                                                                                  |
|                                      | Specifies that a <code>ResultSet</code> 's cursor can move only in the forward direction (i.e., from the first row to the last row in the <code>ResultSet</code> ).                                                                                                              |
| <code>TYPE_SCROLL_INSENSITIVE</code> |                                                                                                                                                                                                                                                                                  |
|                                      | Specifies that a <code>ResultSet</code> 's cursor can scroll in either direction and that the changes made to the <code>ResultSet</code> during <code>ResultSet</code> processing are not reflected in the <code>ResultSet</code> unless the program queries the database again. |
| <code>TYPE_SCROLL_SENSITIVE</code>   |                                                                                                                                                                                                                                                                                  |
|                                      | Specifies that a <code>ResultSet</code> 's cursor can scroll in either direction and that the changes made to the <code>ResultSet</code> during <code>ResultSet</code> processing are reflected immediately in the <code>ResultSet</code> .                                      |

Figure 25.30. `ResultSet` constants for specifying result properties.

| <code>ResultSet</code> static concurrency constant | Description                                                                                                                                                                                                |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CONCUR_READ_ONLY</code>                      | Specifies that a <code>ResultSet</code> cannot be updated (i.e., changes to the <code>ResultSet</code> contents cannot be reflected in the database with <code>ResultSet</code> 's <i>update</i> methods). |
| <code>CONCUR_UPDATABLE</code>                      | Specifies that a <code>ResultSet</code> can be updated (i.e., changes to the <code>ResultSet</code> contents can be reflected in the database with <code>ResultSet</code> 's <i>update</i> methods).       |

## Common Programming Error 25.12

*Attempting to move the cursor backwards through a `ResultSet` when the database driver does not support backwards scrolling causes a `SQLException`.*

Method `getColumnClass` (lines 5373) returns a `Class` object that represents the superclass of all objects in a particular column. The `JTable` uses this information to configure the default cell renderer and cell editor for

that column in the `JTable`. Line 62 uses `ResultSetMetaData` method `getColumnClassName` to obtain the fully qualified class name for the specified column. Line 65 loads the class and returns the corresponding `Class` object. If an exception occurs, the `catch` in lines 6770 prints a stack trace and line 72 returns `Object.class` the `Class` instance that represents class `Object` as the default type. [Note: Line 62 uses the argument `column + 1`. Like arrays, `JTable` row and column numbers are counted from 0. However, `ResultSet` row and column numbers are counted from 1. Thus, when processing `ResultSet` rows or columns for use in a `JTable`, it is necessary to add 1 to the row or column number to manipulate the appropriate `ResultSet` row or column.]

Method `getColumnCount` (lines 7693) returns the number of columns in the model's underlying `ResultSet`. Line 85 uses `ResultSetMetaData` method `getColumnCount` to obtain the number of columns in the `ResultSet`. If an exception occurs, the `catch` in lines 8790 prints a stack trace and line 92 returns 0 as the default number of columns.

Method `getColumnName` (lines 96113) returns the name of the column in the model's underlying `ResultSet`. Line 105 uses `ResultSetMetaData` method `getColumnName` to obtain the column name from the `ResultSet`. If an exception occurs, the `catch` in lines 107110 prints a stack trace and line 112 returns the empty string as the default column name.

Method `getRowCount` (lines 116123) returns the number of rows in the model's underlying `ResultSet`. When method `setQuery` (lines 148167) performs a query, it stores the number of rows in variable `numberOfRows`.

Method `getValueAt` (lines 126145) returns the `Object` in a particular row and column of the model's underlying `ResultSet`. Line 136 uses `ResultSet` method `absolute` to position the `ResultSet` cursor at a specific row. Line 137 uses `ResultSet` method `getObject` to obtain the `Object` in a specific column of the current row. If an exception occurs, the `catch` in lines 139142 prints a stack trace and line 144 returns an empty string as the default value.

Method `setQuery` (lines 148167) executes the query it receives as an argument to obtain a new `ResultSet` (line 156). Line 159 gets the `ResultSetMetaData` for the new `ResultSet`. Line 162 uses `ResultSet` method `last` to position the `ResultSet` cursor at the last row in the `ResultSet`. Line 163 uses `ResultSet` method `getRow` to obtain the row number for the current row in the `ResultSet`. Line 166 invokes method `fireTableStructureChanged` (inherited from class `AbstractTableModel`) to notify any `JTable` using this `ResultSetTableModel` object as its model that the structure of the model has changed. This causes the `JTable` to repopulate its rows and columns with the new `ResultSet` data. Method `setQuery` throws any exceptions that occur in its body back to the application that invoked `setQuery`.

Method `disconnectFromDatabase` (lines 170189) implements an appropriate termination method for class `ResultSetTableModel`. A class designer should provide a `public` method that clients of the class must invoke explicitly to free resources that an object has used. In this case, method `disconnectFromDatabase` closes the database statement and connection (lines 178179), which are considered limited resources. Clients of the `ResultSetTableModel` class should always invoke this method when the instance of this class is no longer needed. Before releasing resources, line 172 verifies whether the connection is already terminated. If so, the method simply returns. In addition, note that each other method in the class throws an `IllegalStateException` if the boolean field `connectedToDatabase` is `false`. Method `disconnectFromDatabase` sets `connectedToDatabase` to `false` (line 184) to ensure that clients do not use an instance of `ResultSetTableModel` after that instance has already been terminated. `IllegalStateException` is an exception from the Java libraries that is appropriate for indicating this error condition.

The `DisplayQueryResults` (Fig. 25.31) constructor (lines 34140) creates a `ResultSetTableModel` object and the GUI for the application. Lines 2225 and 28 declare the database driver class name, database URL, username, password and default query that are passed to the `ResultSetTableModel` constructor to make the initial connection to the database and perform the default query. Line 64 creates the `JTable` object and passes a `ResultSetTableModel` object to the `JTable` constructor, which then registers the `JTable` as a listener for `TableModelEvents` generated by the `ResultSetTableModel`. Lines 71110 register an event handler for the `submitButton` that the user clicks to submit a query to the database. When the user clicks the button, method `actionPerformed` (lines 76108) invokes `ResultSetTableModel` method `setQuery` to execute the new query. If the user's query fails (e.g., because of a syntax error in the user's input), lines 9394 execute the

default query. If the default query also fails, there could be a more serious error, so line 103 ensures that the database connection is closed and line 105 exits the program. The screen captures in [Fig. 25.31](#) show the results of two queries. The first screen capture shows the default query that retrieves all the data from table `authors` of database `books`. The second screen capture shows a query that selects each author's first name and last name from the `authors` table and combines that information with the title and edition number from the `titles` table. Try entering your own queries in the text area and clicking the **Submit Query** button to execute the query.

## 25.9. Stored Procedures

Many database management systems can store individual SQL statements or sets of SQL statements in a database, so that programs accessing that database can invoke them. Such named collections of SQL are called **stored procedures**. JDBC enables programs to invoke stored procedures using objects that implement interface **CallableStatement**. **CallableStatements** can receive arguments specified with the methods inherited from interface **PreparedStatement**. In addition, **CallableStatements** can specify **output parameters** in which a stored procedure can place return values. Interface **CallableStatement** includes methods to specify which parameters in a stored procedure are output parameters. The interface also includes methods to obtain the values of output parameters returned from a stored procedure.

### Portability Tip 25.7

*Although the syntax for creating stored procedures differs across database management systems, interface **CallableStatement** provides a uniform interface for specifying input and output parameters for stored procedures and for invoking stored procedures.*

### Portability Tip 25.8

*According to the Java API documentation for interface **CallableStatement**, for maximum portability between database systems, programs should process the update counts or **ResultSet**s returned from a **CallableStatement** before obtaining the values of any output parameters.*

## 25.10. RowSet Interface

In the previous examples, you learned how to query a database by explicitly establishing a `Connection` to the database, preparing a `Statement` for querying the database and executing the query. In this section, we demonstrate the `RowSet` interface, which configures the database connection and prepares query statements automatically. Interface `RowSet` provides several *set* methods that allow the programmer to specify the properties needed to establish a connection (such as the database URL, user name and password of the database) and create a `Statement` (such as a query). Interface `RowSet` also provides several *get* methods that return these properties.

`RowSet` is part of the `javax.sql` package. Although part of Java 2 Standard Edition, the classes and interfaces of package `javax.sql` are most frequently used in the context of the Java 2 Platform Enterprise Edition (J2EE). J2EE is used in industry to build substantial distributed applications that often process database data. J2EE is beyond the scope of this book. You can learn more about J2EE by visiting [java.sun.com/j2ee/](http://java.sun.com/j2ee/).

---

[Page 1225]

There are two types of `RowSet` objects: connected and disconnected. A `connected RowSet` object connects to the database once and remains connected until the application terminates. A `disconnected RowSet` object connects to the database, executes a query to retrieve the data from the database and then closes the connection. A program may change the data in a disconnected `RowSet` while it is disconnected. Modified data can be updated in the database after a disconnected `RowSet` reestablishes the connection with the database.

J2SE 5.0 package `javax.sql.rowset` contains two subinterfaces of `RowSet`: `JdbcRowSet` and `CachedRowSet`. `JdbcRowSet`, a connected `RowSet`, acts as a wrapper around a `ResultSet` object, and allows programmers to scroll through and update the rows in the `ResultSet`. Recall that by default, a `ResultSet` object is non-scrollable and read only; you must explicitly set the result-set type constant to `TYPE_SCROLL_INSENSITIVE` and set the result-set concurrency constant to `CONCUR_UPDATABLE` to make a `ResultSet` object scrollable and updatable. A `JdbcRowSet` object is scrollable and updatable by default. `CachedRowSet`, a disconnected `RowSet`, caches the data of a `ResultSet` in memory and disconnects from the database. Like `JdbcRowSet`, a `CachedRowSet` object is scrollable and updatable by default. A `CachedRowSet` object is also serializable, so it can be passed between Java applications through a network, such as the Internet. However, `CachedRowSet` has a limitation: the amount of data that can be stored in memory is limited. Besides `JdbcRowSet` and `CachedRowSet`, package `javax.sql.rowset` contains three other subinterfaces of `RowSet`. For details of these interfaces, visit [java.sun.com/j2se/5.0/docs/guide/jdbc/getstart/rowsetImpl.html](http://java.sun.com/j2se/5.0/docs/guide/jdbc/getstart/rowsetImpl.html).

[Figure 25.32](#) reimplements the example of [Fig. 25.25](#) using a `RowSet`. Rather than establish the connection and create a `Statement` explicitly, [Fig. 25.32](#) uses a `JdbcRowSet` object to create a `Connection` and a `Statement` automatically.

Figure 25.32. Displaying the `authors` table using `JdbcRowSet`.

(This item is displayed on pages 1225 - 1226 in the print version)

14 static final String PASSWORD = "jhtp6";
15
16 // constructor connects to database, queries database, processes
17 // results and displays results in window
18 public JdbcRowSetTest()
19 {
20 // connect to database books and query database
21 try
22 {
23 Class.forName(JDBC_DRIVER); // load database driver class
24
25 // specify properties of JdbcRowSet
26 JdbcRowSet rowSet = new JdbcRowSetImpl();
27 rowSet.setUrl(DATABASE_URL); // set database URL
28 rowSet.setUsername(USERNAME); // set username
29 rowSet.setPassword(PASSWORD); // set password
30 rowSet.setCommand("SELECT * FROM authors"); // set query
31 rowSet.execute(); // execute query
32
33 // process query results
34 ResultSetMetaData metaData = rowSet.getMetaData();
35 int numberOfColumns = metaData.getColumnCount();
36 System.out.println("Authors Table of Books Database:");
37
38 // display rowset header
39 for (int i = 1; i <= numberOfColumns; i++)
40 System.out.printf("%-8s\t", metaData.getColumnName(i));
41 System.out.println();
42
43 // display each row
44 while (rowSet.next())
45 {
46 for (int i = 1; i <= numberOfColumns; i++)
47 System.out.printf("%-8s\t", rowSet.getObject(i));
48 System.out.println();
49 } // end while
50 } // end try
51 catch (SQLException sqlException)
52 {
53 sqlException.printStackTrace();
54 System.exit(1);
55 } // end catch
56 catch (ClassNotFoundException classNotFound)
57 {
58 classNotFound.printStackTrace();
59 System.exit(1);
60 } // end catch
61 } // end DisplayAuthors constructor
62
63 // launch the application
64 public static void main(String args[])
65 {
66 JdbcRowSetTest window = new JdbcRowSetTest();
67 } // end main

```

```
68 } // end class JdbcRowSetTest
```

Authors Table of Books Database:

| authorID | firstName | lastName |
|----------|-----------|----------|
| 1        | Harvey    | Deitel   |
| 2        | Paul      | Deitel   |
| 3        | Tem       | Nieto    |
| 4        | Sean      | Santry   |

[Page 1227]

Line 26 uses Sun's reference implementation of the `JdbcRowSet` interface, `JdbcRowSetImpl` from package `com.sun.rowset`, to create a `JdbcRowSet` object. Package `com.sun.rowset` provides implementations of the interfaces in package `javax.sql.rowset`. We used class `JdbcRowSetImpl` here to demonstrate the capability of the `JdbcRowSet` interface. Some databases may provide their own `RowSet` implementations.

Line 27 invokes `JdbcRowSet` method `setUrl` to specify the database URL, which is then used by the `DriverManager` to establish a connection. Line 28 invokes `JdbcRowSet` method `setUsername` to specify the username, which is then used by the `DriverManager` to establish a connection. Line 29 invokes `JdbcRowSet` method `setPassword` to specify the password, which is then used by the `DriverManager` to establish a connection. Line 30 invokes `JdbcRowSet` method `setCommand` to specify the SQL query. Line 31 invokes `JdbcRowSet` method `execute` to execute the SQL query. Method `execute` performs four actions: it establishes a `Connection`, prepares the query `Statement`, executes the query and stores the `ResultSet` returned by query. The `Connection`, `Statement` and `ResultSet` are encapsulated in the `JdbcRowSet` object. The remaining code is almost identical to [Fig. 25.25](#), except that line 34 obtains a `ResultSetMetaData` object from the `JdbcRowSet`, line 44 uses the `JdbcRowSet`'s `next` method to get the next row of the result, and line 47 uses the `JdbcRowSet`'s `getObject` method to obtain a column's value. Note that the output of this application is exactly the same as that of [Fig. 25.25](#).

In this chapter, you learned basic database concepts, how to interact with data in a database using SQL and how to use JDBC to allow Java applications to manipulate database data. You learned the explicit steps for obtaining a `Connection` to the database, creating a `Statement` to interact with the database's data, executing the statement and processing the results. Finally you saw how to use a `RowSet` to simplify the process of connecting to a database and creating statements. In the next chapter, you will learn about servlets, which are Java programs that enhance a Web Server's capabilities. Servlets sometimes use JDBC to interact with databases on behalf of users who make requests via Web browsers.

◀ PREV

NEXT ▶

## 25.11. Wrap-Up

This chapter introduced the SQL and the JDBC API. You learned basic SQL to retrieve data from and update data in a database. You examined the contents of a sample database and learned how to set it up for use with the MySQL database management system. You also learned how to access and manipulate the MySQL database via the JDBC API. Then, you learned the new `RowSet` interface introduced in J2SE 5.0. In the next chapter, we demonstrate how to build Web applications using Java servlets. We also introduce the concept of a three-tier application, in which an application is divided into three pieces that can reside on the same computer or can be distributed among separate computers across a network, such as the Internet.

## Summary

- A database is an integrated collection of data. A database management system (DBMS) provides mechanisms for storing, organizing, retrieving and modifying data for many users.
  - Today's most popular database management systems are relational database systems.
  - SQL is the international standard language used almost universally with relational database systems to perform queries and manipulate data.
  - Programs connect to, and interact with, relational databases via an interface software that facilitates communications between a database management system and a program.
  - Java programmers communicate with databases and manipulate their data using the JDBC API. A JDBC driver enables Java applications to connect to a database in a particular DBMS and allows programmers to retrieve and manipulate database data.
  - A relational database stores data in tables. Tables are composed of rows and rows are composed of columns in which values are stored.
  - A primary key provides a unique value that cannot be duplicated in other rows of the same table.
  - Each column of a table represents a different attribute.
  - The primary key can be composed of more than one column.
  - SQL provides a rich set of language constructs that enable programmers to define complex queries to retrieve data from a database.
  - Every column in a primary key must have a value, and the value of the primary key must be unique. This is known as the Rule of Entity Integrity.
- 

- A one-to-many relationship between tables indicates that a row in one table can have many related rows in a separate table.
- A foreign key is a column in a table that matches the primary key column in another table.
- The foreign key helps maintain the Rule of Referential Integrity: Every foreign key value must appear as another table's primary key value. Foreign keys enable information from multiple tables to be joined together. There is a one-to-many relationship between a primary key and its corresponding foreign key.
- The basic form of a query is

```
SELECT * FROM tableName
```

where the asterisk (\*) indicates that all columns from *tableName* should be selected, and *tableName* specifies the table in the database from which rows will be retrieved.

- To retrieve specific columns from a table, replace the asterisk (\*) with a comma-separated list of column names.
- Programmers process query results by knowing in advance the order of the columns in the result.

Specifying columns explicitly guarantees that they are always returned in the specified order, even if the actual order in the table(s) is different.

- The optional **WHERE** clause in a query specifies the selection criteria for the query. The basic form of a query with selection criteria is

```
SELECT columnName1, columnName2, ... FROM tableName WHERE criteria
```

- The **WHERE** clause can contain operators **<**, **>**, **<=**, **>=**, **=**, **<>** and **LIKE**. Operator **LIKE** is used for string pattern matching with wildcard characters percent (**%**) and underscore (**\_**).
- A percent character (**%**) in a pattern indicates that a string matching the pattern can have zero or more characters at the percent character's location in the pattern.
- An underscore (**\_**) in the pattern string indicates a single character at that position in the pattern.
- The result of a query can be sorted in ascending or descending order using the optional **ORDER BY** clause. The simplest form of an **ORDER BY** clause is

```
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column ASC
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column DESC
```

where **ASC** specifies ascending order, **DESC** specifies descending order and *column* specifies the column on which the sort is based. The default sorting order is ascending, so **ASC** is optional.

- Multiple columns can be used for ordering purposes with an **ORDER BY** clause of the form

```
ORDER BY column1 sortingOrder, column2 sortingOrder, ...
```

- The **WHERE** and **ORDER BY** clauses can be combined in one query. If used, **ORDER BY** must be the last clause in the query.
- An **INNER JOIN** merges rows from two tables by matching values in columns that are common to the tables. The basic form for the **INNER JOIN** operator is:

```
SELECT columnName1, columnName2,...
FROM table1
INNER JOIN table2
ON table1.columnName = table2.columnName
```

The **ON** clause specifies the columns from each table that are compared to determine which rows are joined. If a SQL statement uses columns with the same name from multiple tables, the column names must be fully qualified by prefixing them with their table names and a dot (**.**).

- An **INSERT** statement inserts a new row into a table. The basic form of this statement is

```
INSERT INTO tableName(columnName1, columnName2, ..., columnNameN)
VALUES (value1, value2, ..., valueN)
```

where *tableName* is the table in which to insert the row. The *tableName* is followed by a comma-separated list of column names in parentheses. The list of column names is followed by the SQL keyword **VALUES** and a comma-separated list of values in parentheses.

- SQL uses single quotes (**'**) as the delimiter for strings. To specify a string containing a single quote in SQL, the single quote must be escaped with another single quote.

- An **UPDATE** statement modifies data in a table. The basic form of an **UPDATE** statement is

```
UPDATE tableName
SET columnName1 = value1, columnName2 = value2, ..., columnNameN = valueN
WHERE criteria
```

where *tableName* is the table in which to update data. The *tableName* is followed by keyword **SET** and a comma-separated list of column name/value pairs in the format *columnName* = *value*. The optional **WHERE** clause *criteria* determines which rows to update.

- A **DELETE** statement removes rows from a table. The simplest form for a **DELETE** statement is

```
DELETE FROM tableName WHERE criteria
```

where *tableName* is the table from which to delete a row (or rows). The optional **WHERE** *criteria* determines which rows to delete.

- Package **java.sql** contains classes and interfaces for accessing relational databases in Java.
- A program must load a JDBC driver class before the program can connect to a database.
- JDBC supports four categories of drivers: JDBC-to-ODBC bridge driver (Type 1), Native-API, partly Java driver (Type 2), Pure Java client to server driver (Type 3) and Pure Java driver (Type 4).
- An object that implements interface **Connection** manages the Connection between a Java program and a database. **Connection** objects enable programs to create SQL statements that access data.
- Method **getConnection** of class **DriverManager** attempts to connect to a database specified by its URL argument. The URL helps the program locate the database. The URL includes the protocol for communication, the subprotocol for communication and the name of the database.
- **Connection** method **createStatement** creates an object of type **Statement**. The program uses the **Statement** object to submit SQL statements to the database.
- **Statement** method **executeQuery** executes a query and returns an object that implements interface **ResultSet** containing the query result. **ResultSet** methods enable a program to manipulate query results.
- A **ResultSetMetaData** object describes a **ResultSet**'s contents. Programs can use metadata programmatically to obtain information about the **ResultSet** column names and types.
- **ResultSetMetaData** method **getColumnCount** retrieves the number of **ResultSet** columns.
- **ResultSet** method **next** positions the **ResultSet** cursor to the next row in the **ResultSet**. The cursor points to the current row. Method **next** returns **boolean** value **TRUE** if it is able to position to the next row; otherwise, the method returns **false**. This method must be called to begin processing a **ResultSet**.
- When processing **ResultSets**, it is possible to extract each column of the **ResultSet** as a specific Java type. **ResultSetMetaData** method **getColumnType** returns a constant integer from class **Types** (package **java.sql**) indicating the type of the data for a specific column.
- **ResultSet** *get* methods typically receive as an argument either a column number (as an **int**) or a column name (as a **String**) indicating which column's value to obtain.

- **ResultSet** row and column numbers start at 1.
- Each **Statement** object can open only one **ResultSet** object at a time. When a **Statement** returns a new **ResultSet**, the **Statement** closes the prior **ResultSet**.

- `Connection` method `createStatement` has an overloaded version that takes two arguments: the result type and the result concurrency. The result type specifies whether the `ResultSet`'s cursor is able to scroll in both directions or forward only and whether the `ResultSet` is sensitive to changes. The result concurrency specifies whether the `ResultSet` can be updated with `ResultSet`'s update methods.
- Some JDBC drivers do not support scrollable or updatable `ResultSets`.
- `TableModel` method `getColumnClass` returns a `Class` object that represents the superclass of all objects in a particular column. `JTable` uses this information to set up the default cell renderer and cell editor for that column in a `JTable`.
- `ResultSetMetaData` method `getColumnClassName` obtains the fully qualified class name of the specified column.
- `TableModel` method `getColumnCount` returns the number of columns in the model's underlying `ResultSet`.
- `TableModel` method `getColumnName` returns the name of the column in the model's underlying `ResultSet`.
- `ResultSetMetaData` method `getColumnName` obtains the column name from the `ResultSet`.
- `TableModel` method `getRowCount` returns the number of rows in the model's underlying `ResultSet`.
- `TableModel` method `getValueAt` returns the `Object` at a particular row and column of the model's underlying `ResultSet`.
- `ResultSet` method `absolute` positions the `ResultSet` cursor at a specific row.
- `AbstractTableModel` method `fireTableStructureChanged` notifies any `JTable` using a particular `TableModel` object as its model that the data in the model has changed.
- JDBC enables programs to invoke stored procedures using objects that implement interface `CallableStatement`.
- `CallableStatement` can specify input parameters, like `PreparedStatement`. In addition, `CallableStatement` can specify output parameters in which a stored procedure can place return values.
- Interface `RowSet` configures the database connection and executes the query automatically.
- There are two types of `RowSets` connected and disconnected.
- A connected `RowSet` connects to the database once and remains connected until the application terminates.
- A disconnected `RowSet` connects to the database, executes a query to retrieve the data from the database and then closes the connection.
- `JdbcRowSet`, a connected `RowSet`, acts as a wrapper for a `ResultSet` object, and allows programmers to scroll and update the rows in the `ResultSet`. Unlike a `ResultSet` object, a `JdbcRowSet` object is scrollable and updatable by default.
- `CachedRowSet`, a disconnected `RowSet`, caches the data of a `ResultSet` in memory. Like `JdbcRowSet`, a `CachedRowSet` object is scrollable and updatable. A `CachedRowSet` object is also serializable, so it can be passed between Java applications through a network, such as the Internet.

## Self-Review Exercises

25.1 Fill in the blanks in each of the following statements:

- a. The international standard database language is \_\_\_\_\_.
- b. A table in a database consists of \_\_\_\_\_ and \_\_\_\_\_.
- c. Statement objects return SQL query results as \_\_\_\_\_ objects.
- d. The \_\_\_\_\_ uniquely identifies each row in a table.
- e. SQL keyword \_\_\_\_\_ is followed by the selection criteria that specify the rows to select in a query.
- f. SQL keywords \_\_\_\_\_ specify the order in which rows are sorted in a query.
- g. Merging rows from multiple database tables is called \_\_\_\_\_ the tables.
- h. A(n) \_\_\_\_\_ is an organized collection of data.
- i. A(n) \_\_\_\_\_ is a set of columns whose values match the primary key values of another table.
- j. A(n) \_\_\_\_\_ object is used to obtain a `Connection` to a database.
- k. Interface \_\_\_\_\_ helps manage the connection between a Java program and a database.
- l. A(n) \_\_\_\_\_ object is used to submit a query to a database.
- m. Unlike a `ResultSet` object, \_\_\_\_\_ and \_\_\_\_\_ objects are scrollable and updatable by default.
- n. \_\_\_\_\_, a disconnected `RowSet`, caches the data of a `ResultSet` in memory.

## Answers to Self-Review Exercises

25.1 a) SQL. b) rows, columns. c) `ResultSet`. d) primary key. e) `WHERE`. f) `ORDER BY`. g) joining. h) database. i) foreign key. j) `DriverManager`. k) `Connection`. l) `Statement`. m) `JdbcRowSet`, `CachedRowSet` n) `CachedRowSet`.

## Exercises

- 25.2 Using the techniques shown in this chapter, define a complete query application for the books database. Provide the following predefined queries:
- Select all authors from the `authors` table.
  - Select all publishers from the `publishers` table.
  - Select a specific author and list all books for that author. Include the title, year and ISBN. Order the information alphabetically by the author's last name and first name.
  - Select a specific publisher and list all books published by that publisher. Include the title, year and ISBN. Order the information alphabetically by title.
  - Provide any other queries you feel are appropriate.

Display a `JComboBox` with appropriate names for each predefined query. Also allow users to supply their own queries.

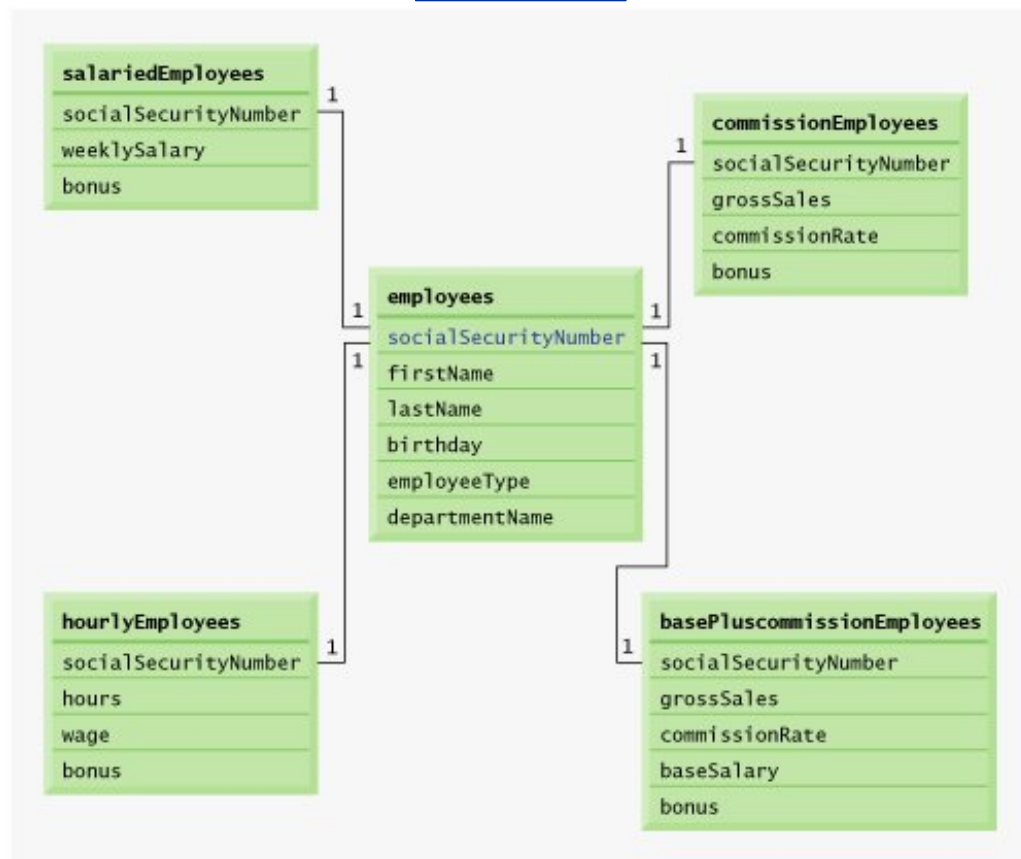

- 25.3 Define a complete data manipulation application for the `books` database. The user should be able to edit existing data and add new data to the database (obeying referential and entity integrity constraints). Allow the user to edit the database in the following ways:
- Add a new author.
  - Edit the existing information for an author.
  - Add a new title for an author. (Remember that the book must have an entry in the `authorISBN` table.) Be sure to specify the publisher of the title.
  - Add a new publisher.
  - Edit the existing information for a publisher.
  - Add a new entry in the `authorISBN` table to link authors with titles.

- 25.4 In [Section 10.7](#), we introduced an employee-payroll hierarchy to calculate each employee's payroll. In this exercise, we provide a database of employees that corresponds to the employee payroll hierarchy. (A SQL script to create the `employees` database is provided with the examples for this chapter on the CD that accompanies this text and on our Web site, [www.deitel.com](http://www.deitel.com).) Write an application that allows the user to:
- Add employees to the Employee table.
  - Add payroll information to the appropriate table for each new employee. For example, for a salaried employee add the payroll information to the `salariedEmployees` table.

[Figure 25.33](#) is the entity-relationship diagram for the `employees` database.

Figure 25.33. Table relationships in `employees`.

[\[View full size image\]](#)

- 25.5 Modify [Exercise 25.4](#) to provide a `JComboBox` and a `JTextArea` to allow the user to perform a query that is either selected from the `JComboBox` or defined in the `JTextArea`. Sample predefined queries are:
- Select all employees working in Department SALES.
  - Select hourly employees working over 30 hours.
  - Select all commission employees in descending order of the commission rate.
- 25.6 Modify [Exercise 25.5](#) to perform the following tasks:
- Increase base salary by 10% for all base plus commission employees.
  - If the employee's birthday is in the current month, add a \$100 bonus.
  - For all commission employees with gross sales over \$10,000, add a \$100 bonus.

## OBJECTIVES

In this chapter you will learn:

- How servlets can be used to extend a Web server's functionality.
- The servlet life cycle.
- To execute servlets with the Apache Tomcat server.
- To be able to respond to HTTP requests from an `HttpServlet`.
- To be able to redirect requests to static and dynamic Web resources.
- To use JDBC from a servlet.

## Outline

### [26.1](#) Introduction

### [26.2](#) Servlet Overview and Architecture

#### [26.2.1](#) Interface `Servlet` and the Servlet Life Cycle

#### [26.2.2](#) `HttpServlet` Class

#### [26.2.3](#) `HttpServletRequest` Interface

#### [26.2.4](#) `HttpServletResponse` Interface

### [26.3](#) Setting Up the Apache Tomcat Server

### [26.4](#) Handling `HTTP` `get` Requests

#### [26.4.1](#) Deploying a Web Application

[26.5](#) Handling `HTTP get` Requests Containing Data

## 26.1. Introduction

[Chapter 24](#) presented Java's fundamental networking capabilities from package `java.net`, which offers both socket-and packet-based communication. Higher-level views of networking are provided by classes and interfaces in the `java.rmi` packages (five packages) for [Remote Method Invocation \(RMI\)](#) and the `org.omg` packages (seven packages) for [Common Object Request Broker Architecture \(CORBA\)](#). The RMI packages allow Java objects running on separate JVMs (normally on separate computers) to communicate via remote method calls. Such calls appear to invoke methods on an object in the same program, but actually have built-in networking (based on the capabilities of package `java.net`) that communicates the method calls to another object on a separate computer. The CORBA packages provide functionality similar to that of the RMI packages. A key difference between RMI and CORBA is that RMI can only be used between Java objects, whereas CORBA can be used between any two applications that understand CORBAincluding applications written in other programming languages. [ *Note:* [Remote Method Invocation over the Internet Inter-Orb Protocol \(RMI-IIOP\)](#) enables the integration of Java with non-Java distributed objects by using CORBA IIOP.] In [Chapter 13](#) of our book *Advanced Java 2 Platform How to Program*, we present Java's RMI capabilities. [Chapters 2627](#) of *Advanced Java 2 Platform How to Program* discuss the basic CORBA concepts and present a case study that implements a distributed system in CORBA.

## Client-Server Relationship

Our discussion in this chapter continues the focus in [Chapter 24](#) the client-server relationship. The client requests that some action be performed and the server performs the action and responds to the client. This request-response model of communication is the foundation for the highest-level views of networking in [Java servlets](#) and [JavaServer Pages \(JSP\)](#). A servlet extends the functionality of a server, such as a [Web server](#) that serves Web pages to a user's browser using the HTTP protocol. Packages `javax.servlet` and `javax.servlet.http` provide the classes and interfaces to define servlets. Packages `javax.servlet.jsp` and `javax.servlet.jsp.tagext` provide the classes and interfaces that extend the servlet capabilities for JavaServer Pages. Using special syntax, JSP allows Web-page implementors to create pages that encapsulate Java functionality and even to write scriptlets of actual Java code directly in the page.

A common implementation of the request-response model is between Web browsers and Web servers. When a user selects a Web site to browse through the browser (the client application), a request is sent to the appropriate Web server (the server application). The server normally responds to the client by sending the appropriate XHTML Web page. [ *Note:* If you are not familiar with XHTML and CSS, refer to the PDF documents [Introduction to XHTML: Part 1](#), [Introduction to XHTML: Part 2](#) and [Cascading Style Sheets \(CSS\)](#) on the CD that accompanies this book. For the purposes of this chapter and [Chapter 27](#), JavaServer Pages (JSP), we assume you already know XHTML.] Servlets are effective for developing Web-based solutions that help provide secure access to a Web site, interact with databases on behalf of a client, dynamically generate custom XHTML documents to be displayed by browsers and maintain unique session information for each client.

This chapter continues our networking discussions by discussing servlets that enhance the functionality of Web serverthe most common form of servlet. [Chapter 27](#), JavaServer Pages (JSP), discusses JSPs, which are translated into servlets. JSPs are a convenient and powerful way to implement the request-response mechanism of the Web without getting into the lower-level details of servlets. Together, servlets and JSPs form the Web components of the Java 2 Enterprise Edition (J2EE) that run on a J2EE server.

## Thin Clients

Many developers feel that servlets are the right solution for database-intensive applications that communicate with so-called **thin clients** applications that provide presentation but do not process data, thus requiring fewer computing resources. The server is responsible for database access. Clients connect to the server using standard protocols available on most client platforms. Thus, the presentation-logic code for generating dynamic content can be written once and reside on the server for access by clients, to allow programmers to create efficient thin clients.

In this chapter, our servlet examples demonstrate the Web's request-response mechanism (primarily with **get** and **post** requests), redirecting requests to other resources and interacting with databases through JDBC. We placed this chapter after our discussion of JDBC and databases intentionally, so that we can build multitier, client-server applications that access databases.

## Apache Jakarta Project and the Tomcat Server

Sun Microsystems, through the [Java Community Process](#), is responsible for the development of the servlet and JavaServer Pages specifications. The reference implementation of both these standards is developed by the [Apache Software Foundation](#) ([www.apache.org](http://www.apache.org)) as part of the [Jakarta Project](#) ([jakarta.apache.org](http://jakarta.apache.org)). As stated on the Jakarta Project's home page, "The goal of the Jakarta Project is to provide commercial-quality server solutions based on the Java Platform that are developed in an open and cooperative fashion." There are many subprojects under the Jakarta project to help commercial server-side developers. The servlet and JSP part of the Jakarta Project is called **Tomcat**. This is the official reference implementation of the JSP and servlet standards. We use Tomcat to demonstrate the servlets in this chapter. The most recent implementation of Tomcat at the time of this writing was version 5.0.25. For your convenience, Tomcat 5.0.25 is included on the CD that accompanies this book. However, the most recent version always can be downloaded from the Apache Group's Web site. To execute the servlets in this chapter, you must install Tomcat or an equivalent servlet and JavaServer Pages implementation. We discuss the setup and configuration of Tomcat in [Section 26.3](#) and [Section 26.4.1](#), after we introduce our first example.

---

[Page 1239]

In our directions for testing each of the examples in this chapter, we indicate that you should copy files into specific Tomcat directories. All the example files for this chapter are located on the CD that accompanies this book and on our Web site, [www.deitel.com](http://www.deitel.com). At the end of [Section 26.11](#), we provide a list of Internet specifications (as discussed in the Servlet 2.4 Specification) for technologies related to servlet development. Each is listed with its RFC (Request for Comments) number. An RFC is a document that describes standard protocols, mechanisms and procedures for Internet development. We provide the URL of a Web site that allows you to locate each specification for your review.

## 26.2. Servlet Overview and Architecture

This section overviews Java servlet technology, discussing at a high level the servlet-related classes, methods and exceptions. The next several sections present examples in which we build multitier client-server systems using servlet and JDBC technology.

The Internet offers many protocols. The HTTP (Hypertext Transfer Protocol) that forms the basis of the World Wide Web uses URLs (Uniform Resource Locators) to locate resources on the Internet. Common URLs represent files or directories and can represent complex tasks such as database lookups and Internet searches. For more information on URL formats, visit [www.w3.org/Addressing](http://www.w3.org/Addressing). For more information on the HTTP protocol, visit [www.w3.org/Protocols/HTTP](http://www.w3.org/Protocols/HTTP). For information on a variety of World Wide Web topics, visit the World Wide Web Consortium's Web site [www.w3.org](http://www.w3.org).

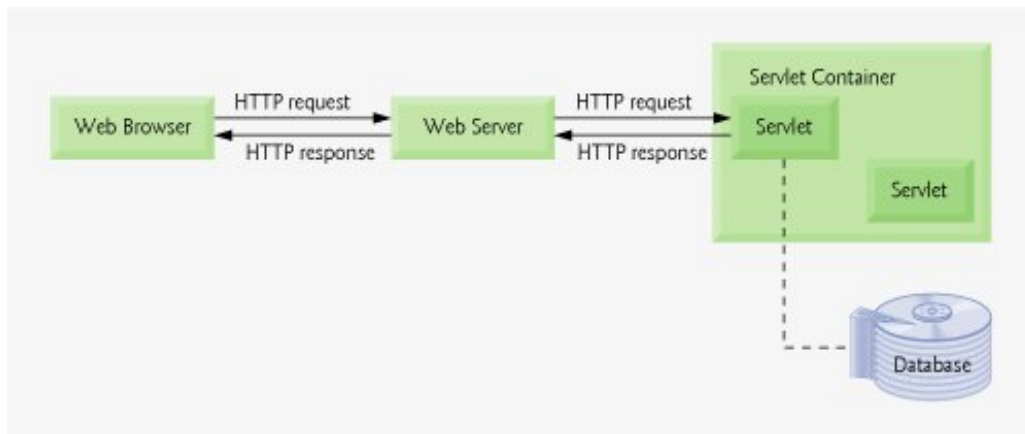

JavaServer Pages technology, an extension of servlet technology, simplifies the process of creating pages by separating presentation from content. Normally, JSPs are used when most of the content sent to the client is static text and markup, and only a small portion of the content is generated dynamically with Java code. Servlets commonly are used when a small portion of the content sent to the client is static text or markup. In fact, some servlets do not produce content. Rather, they perform a task on behalf of the client, then invoke other servlets or JSPs to provide a response. Note that in most cases servlet and JSP technologies are interchangeable. The server that executes a servlet is referred to as the [servlet container](#) or [servlet engine](#).

Servlets and JavaServer Pages have become so popular that they are now supported directly or with third-party plug-ins by most major Web servers and [application servers](#) servers that execute applications to generate dynamic Web pages in response to requests. Several popular Web servers and application servers include the Sun Java System Application Server ([www.sun.com/software/products/appsrvr/home\\_appsrvr.html](http://www.sun.com/software/products/appsrvr/home_appsrvr.html)), Microsoft's Internet Information Services (IIS) ([www.microsoft.com/iis](http://www.microsoft.com/iis)), the Apache HTTP Server ([httpd.apache.org/](http://httpd.apache.org/)), BEA's WebLogic application server ([www.bea.com/products/weblogic/server/index.shtml](http://www.bea.com/products/weblogic/server/index.shtml)), IBM's WebSphere application server ([www-3.ibm.com/software/webservers/appserv/](http://www-3.ibm.com/software/webservers/appserv/)) and the World Wide Web Consortium's Jigsaw Web server ([www.w3.org/Jigsaw/](http://www.w3.org/Jigsaw/)).

The servlets in this chapter demonstrate communication between clients and servers via the HTTP protocol ([Fig. 26.1](#)). A client sends an HTTP request to the server. The servlet container receives the request and directs it to be processed by the appropriate servlet. The servlet does its processing, which may include interacting with a database or other server-side components, such as other servlets or JSPs. The servlet returns its results to the client normally in the form of an HTML, XHTML or XML (Extensible Markup Language, which is used to exchange structured data on the Web) document to display in a browser. Other data formats, such as images and binary data, can also be returned.

Figure 26.1. Servlet architecture.

[\[View full size image\]](#)

## 26.2.1. Interface `Servlet` and the Servlet Life Cycle

Architecturally, all servlets must implement the `Servlet` interface of package `javax.servlet`. The methods of interface `Servlet` are invoked by the servlet container. This interface declares five methods described in [Fig. 26.2](#). You can view the details of the `Servlet` interface online at [java.sun.com/j2ee/1.4/docs/api/javax/servlet/Servlet.html](http://java.sun.com/j2ee/1.4/docs/api/javax/servlet/Servlet.html).

Figure 26.2. `Servlet` interface methods.

(This item is displayed on page 1241 in the print version)

| Method                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>void init( ServletConfig config )</code>                                |                                                                                                                                                                                                                                                                                                                                                                            |
|                                                                               | The servlet container calls this method once during a servlet's execution cycle to initialize the servlet. The <code>ServletConfig</code> argument is supplied by the servlet container that executes the servlet.                                                                                                                                                         |
| <code>ServletConfig getServletConfig()</code>                                 |                                                                                                                                                                                                                                                                                                                                                                            |
|                                                                               | This method returns a reference to an object that implements interface <code>ServletConfig</code> . This object provides access to the servlet's configuration information, such as its initialization parameters and <code>ServletContext</code> , which provides the servlet with access to its environment (i.e., the servlet container in which the servlet executes). |
| <code>String getServletInfo()</code>                                          |                                                                                                                                                                                                                                                                                                                                                                            |
|                                                                               | This method is defined by a servlet programmer to return a string containing servlet information, such as the servlet's author and version.                                                                                                                                                                                                                                |
| <code>void service( ServletRequest request, ServletResponse response )</code> |                                                                                                                                                                                                                                                                                                                                                                            |
|                                                                               | The servlet container calls this method to respond to a client request to the servlet.                                                                                                                                                                                                                                                                                     |
| <code>void destroy()</code>                                                   |                                                                                                                                                                                                                                                                                                                                                                            |
|                                                                               | This "cleanup" method is called when a servlet is terminated by its servlet container. Resources used by the servlet, such as open files or open database connections, should be deallocated here.                                                                                                                                                                         |

*Servlets implement the `Servlet` interface of package `javax.servlet`*

A servlet's life cycle begins when the servlet container loads it into memory normally, in response to the first request for the servlet. Before the servlet can handle that request, the container invokes the servlet's `init` method. After `init` completes execution, the servlet can respond to its first request. All requests are handled by a servlet's `service` method, which receives the request, processes it and sends a response to the client. During a servlet's life cycle, method `service` is called once per request. Each new request is typically handled in a separate thread of execution (managed by the servlet container) in which method `service` executes. When the servlet container terminates the servlet (e.g., when the servlet container needs more memory or when it is shut down), the servlet's `destroy` method is called to release servlet resources.

---

[Page 1241]

The servlet packages define two `abstract` classes that implement interface `Servlet` class `GenericServlet` (from the package `javax.servlet`) and class `HttpServlet` (from the package `javax.servlet.http`). These classes provide default implementations of some `Servlet` methods. Most servlets extend either `GenericServlet` or `HttpServlet` and override some or all of their methods. The `GenericServlet` is a protocol-independent servlet, while the `HttpServlet` uses the HTTP protocol to exchange the information between the server and the client. `HttpServlet` is used on the Web. If your servlets need to implement protocols other than HTTP, they may extend `GenericServlet`. To extend `GenericServlet`, the servlet must override the `abstract` method `service`. To extend `HttpServlet`, the servlet must override at least one method declared in class `HttpServlet`.

The examples in this chapter all extend class `HttpServlet`, which defines enhanced processing capabilities for servlets that extend a Web server's functionality. The key method in every servlet is `service`, which accepts both a `ServletRequest` object and a `ServletResponse` object. These objects provide access to input and output streams that allow the servlet to read data from and send data to the client. These streams can be either byte based or character based. If problems occur during the execution of a servlet, either `ServletExceptions` or `IOExceptions` are thrown to indicate the problem.

---

[Page 1242]

### 26.2.2. `HttpServlet` Class

Servlets typically extend class `HttpServlet`, which overrides method `service` to distinguish between the typical requests received from a client Web browser. The two most common `HTTP request types` (also known as `request methods`) are `get` and `post`. A `get` request gets (or retrieves) information from a server. Such requests often retrieve an HTML document or an image. A `post` request posts (or sends) data to a server, such as authentication information or data from a form that gathers user input. Usually, `post` requests are used to post a message to a news group or a discussion forum, pass user input to a data-handling process and store or update the data on a server.

Class `HttpServlet` defines methods `doGet` and `doPost` to respond to `get` and `post` requests from a client, respectively. These methods are called by method `service`, which is called by the servlet container when a request arrives at the server. Method `service` first determines the request type, then calls the appropriate method for handling such a request. Methods of class `HttpServlet` that respond to the other request types are shown in [Fig. 26.3](#). For more details about these methods, visit <http://java.sun.com/j2ee/1.4/docs/api/javax/servlet/http/HttpServlet.html>. Each method accepts parameters of type `HttpServletRequest` and `HttpServletResponse` and returns `void`. These methods are not frequently used.

Figure 26.3. `HttpServlet` class's other methods.

| Method                 | Description                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>doDelete</code>  | Called in response to an HTTP <code>delete</code> request. Such a request is normally used to delete a file from a server. This may not be available on some servers because of its inherent security risks (e.g., the client could delete a file that is critical to the execution of the server or an application).                                                                  |
| <code>doHead</code>    | Called in response to an HTTP <code>head</code> request. Such a request is normally used when the client wants only the response's headers, such as its content type and content length. By overriding this method, the servlet does not compute the response body, thus improving performance.                                                                                        |
| <code>doOptions</code> | Called in response to an HTTP <code>options</code> request. This returns information to the client indicating the HTTP options supported by the server, such as the HTTP version (1.0 or 1.1) and the request methods the server supports.                                                                                                                                             |
| <code>doPut</code>     | Called in response to an HTTP <code>put</code> request. Such a request is normally used to store a file on the server. This may not be available on some servers because of its inherent security risks (e.g., the client could place an executable application on the server, which, if executed, could damage the server perhaps by deleting critical files or occupying resources). |
| <code>doTrace</code>   | Called in response to an HTTP <code>trace</code> request. Such a request is normally used for debugging. The implementation of this method automatically returns an HTML document to the client containing the request header information (data sent by the browser as part of the request).                                                                                           |

## Software Engineering Observation 26.2

*Do not override method `service` in an `HttpServlet` subclass. Doing so prevents the servlet from distinguishing between request types.*

Methods `doGet` and `doPost` accept as arguments an `HttpServletRequest` object and an `HttpServletResponse` object that enable interaction between the client and the server. The methods of `HttpServletRequest` allow access to the data supplied as part of the request. The `HttpServletResponse` methods make it easy to return the servlet's results to the Web client. Interfaces `HttpServletRequest` and `HttpServletResponse` are discussed in the next two sections.

### 26.2.3. `HttpServletRequest` Interface

Every call to `doGet` or `doPost` for an `HttpServlet` receives an object that implements interface `HttpServletRequest`. The servlet container creates an `HttpServletRequest` object and passes it to the servlet's `service` method (which, in turn, passes it to `doGet` or `doPost`). This object contains the client's

request and provides methods that enable the servlet to process the request. Some methods are from interface `ServletRequest` the interface that `HttpServletRequest` extends. A few key methods used in this chapter are presented in [Fig. 26.4](#). You can view a complete list of `HttpServletRequest` methods online at [java.sun.com/j2ee/1.4/docs/api/javax/servlet/http/HttpServletRequest.html](http://java.sun.com/j2ee/1.4/docs/api/javax/servlet/http/HttpServletRequest.html). You can also install Tomcat (discussed in [Section 26.3](#)) and view the documentation on your local computer.

Figure 26.4. `HttpServletRequest` methods.

(This item is displayed on page 1244 in the print version)

| Method                                                  | Description                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>String getParameter( String name )</code>         |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | Obtains the value of a parameter sent to the servlet as part of a <code>get</code> or <code>post</code> request. The <code>name</code> argument represents the parameter name.                                                                                                                                                                               |
| <code>Enumeration getParameterNames()</code>            |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | Returns the names of all the parameters sent to the servlet as part of a <code>post</code> request.                                                                                                                                                                                                                                                          |
| <code>String[] getParameterValues( String name )</code> |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | For a parameter with multiple values, this method returns an array of strings containing the values for a specified servlet parameter.                                                                                                                                                                                                                       |
| <code>Cookie[] getCookies()</code>                      |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | Returns an array of <code>Cookie</code> objects stored on the client by the server. <code>Cookie</code> objects can be used to uniquely identify clients to the servlet.                                                                                                                                                                                     |
| <code>HttpSession getSession( boolean create )</code>   |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | Returns an <code>HttpSession</code> object associated with the client's current browsing session. This method can create an <code>HttpSession</code> object ( <code>TRUE</code> argument) if one does not already exist for the client. <code>HttpSession</code> objects and <code>Cookies</code> are used in similar ways for uniquely identifying clients. |
| <code>String getLocalName()</code>                      |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | Gets the host name on which the request was received.                                                                                                                                                                                                                                                                                                        |
| <code>String getLocalAddr()</code>                      |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | Gets the Internet Protocol (IP) address on which the request was received.                                                                                                                                                                                                                                                                                   |
| <code>int getLocalPort()</code>                         |                                                                                                                                                                                                                                                                                                                                                              |
|                                                         | Gets the Internet Protocol (IP) port number on which the request was received.                                                                                                                                                                                                                                                                               |

### 26.2.4. `HttpServletResponse` Interface

Every call to `doGet` or `doPost` for an `HttpServlet` receives an object that implements interface `HttpServletResponse`. The servlet container creates an `HttpServletResponse` object and passes it to the servlet's service method (which, in turn, passes it to `doGet` or `doPost`). This object provides methods that enable the servlet to formulate the response to the client. Some of these are from interface `ServletResponse` the interface that `HttpServletResponse` extends. A few key methods used in this chapter are presented in [Fig. 26.5](#). You can view a complete list of `HttpServletResponse` methods online at

[java.sun.com/j2ee/1.4/docs/api/javax/servlet/http/HttpServletResponse.html](http://java.sun.com/j2ee/1.4/docs/api/javax/servlet/http/HttpServletResponse.html). You can also view the documentation on your local computer through Tomcat.

Figure 26.5. **HttpServletResponse** methods.

(This item is displayed on page 1245 in the print version)

| Method                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>void addCookie( Cookie cookie )</code>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                                    | Used to add a <b>Cookie</b> to the header of the response to the client. The <b>Cookie</b> 's maximum age and whether <b>Cookies</b> are enabled on the client determine whether <b>Cookies</b> are stored on the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>ServletOutputStream getOutputStream()</code> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                                    | Obtains a byte-based output stream for sending binary data to the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>PrintWriter getWriter()</code>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                                    | Obtains a character-based output stream for sending text data (usually HTML formatted text) to the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>void setContentType( String type )</code>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                                    | Specifies the content type of the response to the browser. The content type helps the browser determine how to display the data (or possibly what other application to execute to process the data). The content type is also known as MIME (Multipurpose Internet Mail Extension) type of the data. For examples, content type <code>"text/html"</code> indicates that the response is an HTML document, so the browser displays the HTML page; content type <code>"image/gif"</code> indicates that the response is an image, so the browser displays the image. For a complete list of content types, visit <a href="http://www.isi.edu/in-notes/iana/assignments/mediatypes/mediatypes">www.isi.edu/in-notes/iana/assignments/mediatypes/mediatypes</a> . |
| <code>String getContentType()</code>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                                    | Gets the content type of the response.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## 26.3. Setting Up the Apache Tomcat Server

Tomcat is a fully functional implementation of servlets and JavaServer Pages (JSP). It includes a Web server, so it can be used as a standalone test container for servlets and JSPs. Tomcat can also be specified as the handler for JSP and servlet requests received by popular Web servers such as the Apache Software Foundation's Apache HTTP server or Microsoft's Internet Information Services (IIS). Tomcat is also integrated into the Java 2 Enterprise Edition reference implementation from Sun Microsystems.

The most recent release of Tomcat at the time of printing (version 5.0.25) can be downloaded from

[apache.towardex.com/jakarta/tomcat-5/v5.0.25/bin/](http://apache.towardex.com/jakarta/tomcat-5/v5.0.25/bin/)

---

[Page 1244]

where there are several archive files. The complete Tomcat implementation is contained in the files that begin with the name `jakarta-tomcat-5.0.25`. Apache provides `zip`, `exe`, `tar` and compressed `tar` files.

Following the steps below to install Tomcat:

1. Download `jakarta-tomcat-5.0.25.zip` (or the version appropriate for your system) to your hard disk.
2. Use a file extractor tool (such as WinZip, available at [www.winzip.com](http://www.winzip.com)) to extract the content of `jakarta-tomcat-5.0.25.zip` to the `C:\` drive. This will create a directory named `jakarta-tomcat-5.0.25`.

For Tomcat to work correctly, you must define environment variables `JAVA_HOME` and `CATALINA_HOME`. `JAVA_HOME` should point to the directory containing your Java installation (ours is `C:\Program Files\Java\jdk1.5.0`), and `CATALINA_HOME` should point to the directory that contains Tomcat (ours is `C:\jakarta-tomcat-5.0.25`). To define these variables on Windows,

---

[Page 1245]

1. Right click on the **My Computer** icon on your desktop and select **Properties** from the menu. The **System Properties** dialog appears.
2. Select the **Advanced** tab at the top of the System Properties dialog. Click the **Environment Variables** button to display the **Environment Variables** dialog.
3. Click the **New** button under the User variables box. This will cause the **Edit User Variable** dialog to appear.
4. Enter `JAVA_HOME` for Variable name and `C:\Program Files\Java\jdk1.5.0` for **Variable value**. Click the **OK** button to complete the setting of the `JAVA_HOME` variable. This will return to the **Environment Variables** dialog.
5. Click the **New** button under the **User variables** box. This will cause the **Edit User Variable** dialog to appear.

---

[Page 1246]

6. Enter `CATALINA_HOME` for Variable name and `C:\jakarta-tomcat-5.0.25` for **Variable value**. Click the **OK** button to complete the setting of the `CATALINA_HOME` variable. This will return to the **Environment**

Variables dialog.

7. Click the **OK** buttons to close the **Environment Variables** and **System Properties** dialogs.

## Error-Prevention Tip 26.1

*On some platforms you may need to restart your computer for the new environment variables to take effect.*

After setting the environment variables, you can start the Tomcat server. In a command prompt (or shell), change to the bin directory in `jakarta-tomcat-5.0.25`. In this directory are the files `startup.bat`, `shutdown.bat`, `startup.sh` and `shutdown.sh`, for starting and stopping the Tomcat server on Windows and UNIX/Linux/Mac OS X, respectively. To start the server, type

```
startup
```

This launches the Tomcat server, which executes on TCP port 8080 to prevent conflicts with standard Web servers that typically execute on TCP port 80. [ *Note:* If port 8080 is already in use by another application, you can change the port number for Tomcat by modifying the file `server.xml`, which is located in the Tomcat installation directory's `conf` directory. To do so, edit line 92 of `server.xml` (which contains the text `<Connector port="8080">`) and replace "8080" with the port number you want to use.] To verify that Tomcat is executing and can respond to requests, open your Web browser and enter the URL

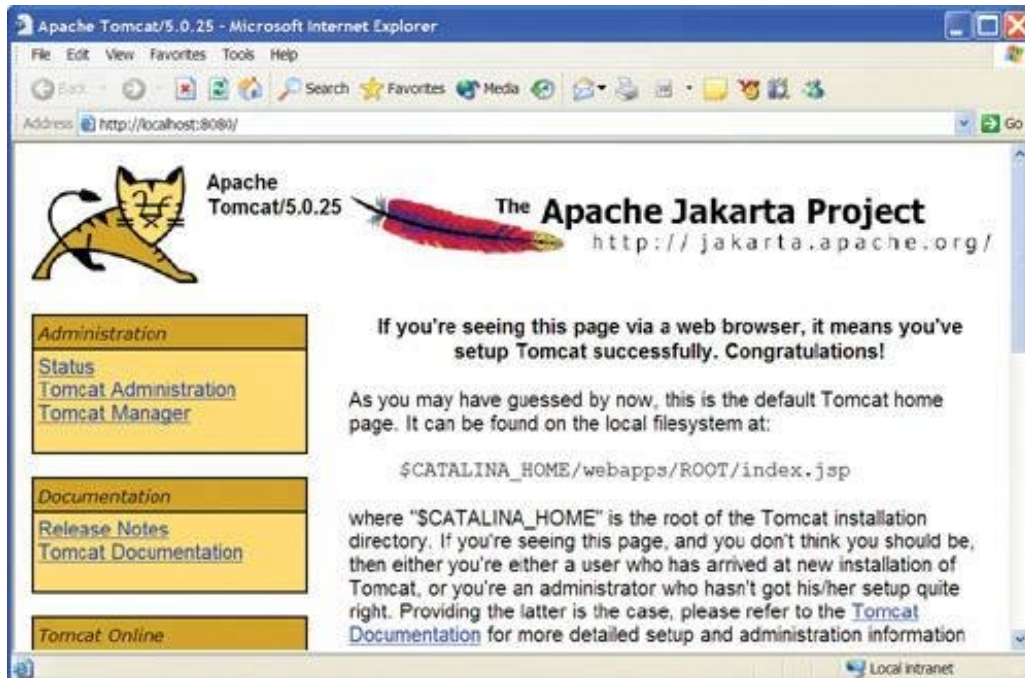

```
http://localhost:8080/
```

[ *Note:* If you changed the port number, use the new port number you specified.] This should display the Tomcat documentation home page ([Fig. 26.6](#)). The host `localhost` indicates to the Web browser that it should request the home page from the Tomcat server on the local computer.

[\[View full size image\]](#)

## Error-Prevention Tip 26.2

*If the host name `localhost` does not work on your computer, substitute the IP address `127.0.0.1` instead.*

To shut down the Tomcat server, issue the command

`shutdown`

from the command prompt (or shell) that starts the Tomcat server.

## 26.4. Handling HTTP `get` Requests

The primary purpose of an HTTP `get` request is to retrieve the content of a specified URL—normally an HTML or XHTML document. The servlet in [Fig. 26.7](#) and the XHTML document in [Fig. 26.8](#) demonstrate a servlet that handles HTTP `get` requests. When the user clicks the **Get HTML Document** button ([Fig. 26.8](#)), a `get` request is sent to the servlet `WelcomeServlet` ([Fig. 26.7](#)). The servlet responds to the request by dynamically generating an XHTML document for the client that displays `"Welcome to Servlets!"`. [Figure 26.7](#) shows the `WelcomeServlet` source code. [Figure 26.8](#) shows the XHTML document the client loads to access the servlet and shows screen captures of the client's browser window before and after the servlet interaction. [ *Note:* [Section 26.3](#) discusses how to set up and configure Tomcat to execute this example.]

---

Figure 26.7. `WelcomeServlet` that responds to a simple HTTP `get` request.

(This item is displayed on page 1248 in the print version)

```
1 // Fig. 26.7: WelcomeServlet.java
2 // A simple servlet to process get requests.
3 import javax.servlet.ServletException;
4 import javax.servlet.http.HttpServlet;
5 import javax.servlet.http.HttpServletRequest;
6 import javax.servlet.http.HttpServletResponse;
7 import java.io.IOException;
8 import java.io.PrintWriter;
9
10 public class WelcomeServlet extends HttpServlet
11 {
12 // process "get" requests from clients
13 protected void doGet(HttpServletRequest request,
14 HttpServletResponse response)
15 throws ServletException, IOException
16 {
17 response.setContentType("text/html");
18 PrintWriter out = response.getWriter();
19
20 // send XHTML page to client
21
22 // start XHTML document
23 out.println("<?xml version = \"1.0\"?>");
24
25 out.printf("%s%s%s" , "<!DOCTYPE html PUBLIC",
26 " \"-//W3C//DTD XHTML 1.0 Strict//EN\"",
27 " \"http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd\">\n");
28
29 out.println("<html xmlns = \"http://www.w3.org/1999/xhtml\">");
30
31 // head section of document
32 out.println("<head>");
33 out.println("<title>A Simple Servlet Example</title>");
34 out.println("</head>");
35 }
```

```

36 // body section of document
37 out.println("<body>");
38 out.println("<h1>Welcome to Servlets!</h1>");
39 out.println("</body>");
40
41 // end XHTML document
42 out.println("</html>");
43 out.close(); // close stream to complete the page
44 } // end method doGet
45 } // end class WelcomeServlet

```

Figure 26.8. HTML document in which the form's **action** invokes **WelcomeServlet** through the alias **welcome1** specified in **web.xml**.

16 </label></p>
17 </form>
18 </body>
19 </html>

```

[\[View full size image\]](#)

Lines 36 import various classes in the `javax.servlet` and `javax.servlet.http` packages. We use several data types from these packages in the example. Package `javax.servlet.http` provides superclass `HttpServlet` for servlets that handle HTTP `get` requests and HTTP `post` requests. This class implements interface `javax.servlet.Servlet` and adds methods that support HTTP protocol requests. Class `WelcomeServlet` extends `HttpServlet` (line 10) for this reason.

Superclass `HttpServlet` provides method `doGet` to respond to `get` requests. Its default functionality is to indicate a "Method not supported" error. Typically, this error is indicated in Internet Explorer and in Netscape with a Web page that states "HTTP status 405." Lines 1344 override method `doGet` to provide custom `get` request processing. Method `doGet` accepts two arguments: an `HttpServletRequest` object and an `HttpServletResponse` object (both from package `javax.servlet.http`). The `HttpServletRequest` object represents the client's request, and the `HttpServletResponse` object represents the server's response to the client. If method `doGet` is unable to handle a client's request, it throws an exception of type `javax.servlet.ServletException`. If `doGet` encounters an error during stream processing (reading from the client or writing to the client), it throws a `java.io.IOException`.

---

[Page 1248]

To demonstrate a response to a `get` request, our servlet creates an XHTML document containing the text "Welcome to Servlets!" The text of the XHTML document is the response to the client. The response is sent to the client through the `PrintWriter` object obtained from the `HttpServletResponse` object.

Line 17 uses the `response` object's `setContentType` method to specify the content type of the data to be sent as the response to the client. This enables the client browser to understand and handle the content. The content type is also known as the **MIME (Multipurpose Internet Mail Extension)** type of the data. In this example, the content type is `text/html` to indicate to the browser that the response is an XHTML document. The browser knows that it must read the XHTML tags, format the document accordingly and display it in the browser window.

---

[Page 1249]

Line 18 uses the `response` object's `getWriter` method to obtain a reference to the `PrintWriter` object that enables the servlet to send content to the client. [Note: If the response is binary data, such as an image, method `getOutputStream` is used to obtain a reference to a `ServletOutputStream` object.]

Lines 23-42 create the XHTML document by writing strings with the `out` object's `println` method. This method outputs a newline character after its `String` argument. When rendering the Web page, the browser does not use the newline character. Rather, the newline character appears in the XHTML source that you can see by selecting **Source** from the **View** menu in Internet Explorer or **Page Source** from the **View** menu in Netscape. Line 43 closes the output stream, flushes the output buffer and sends the information to the client.

The XHTML document in [Fig. 26.8](#) provides a `form` that invokes the servlet defined in [Fig. 26.7](#). The `form`'s `action` attribute (`/jhttp6/welcome1`) specifies the URL path that invokes the servlet, and the `form`'s `method` attribute indicates that the browser sends a get request to the server, which results in a call to the servlet's `doGet` method. The URL specified as the `action` in this example is discussed in detail in [Section 26.4.1](#) after we show how to set up and configure the Apache Tomcat server to execute the servlet in [Fig. 26.7](#).

Note that the sample screen captures show a URL containing the server name `localhost` a well-known server host name on most computers that support TCP/IP-based networking protocols such as HTTP. We often use `localhost` to demonstrate networking programs on the local computer, so that readers without a network connection can still learn network programming concepts. In this example, `localhost` indicates that the server on which the servlet is installed is running on the local machine. The server host name is followed by `:8080`, specifying the TCP port number at which the Tomcat server listens for requests from clients. Web browsers assume TCP port 80 by default as the server port at which clients make requests, but the Tomcat server listens for client requests at TCP port 8080. This allows Tomcat to execute on the same computer as a standard Web server application without affecting the Web server's ability to handle requests. If we do not explicitly specify the port number in the URL, the servlet will not receive our request and an error message will be displayed in the browser.

## Software Engineering Observation 26.3

*The Tomcat documentation specifies how to integrate Tomcat with popular Web server applications such as the Apache HTTP Server and Microsoft's IIS.*

Ports in this case are not physical hardware ports to which you attach cables; they are logical locations named with integer values that allow clients to request different services on the same server. The port number specifies the logical location where a server waits for and receives connections from clients; this is also called the handshake point. A client connecting to a server to request a service must specify the port number for that service; otherwise, the request cannot be processed. Port numbers are positive integers with values up to 65,535, and there are separate sets of these numbers for both the TCP and UDP protocols. Many operating systems reserve port numbers below 1024 for system services (such as e-mail and World Wide Web servers). Generally, these ports should not be specified as connection ports in your own server programs. In fact, some operating systems require special access privileges to use port numbers below 1024.

With so many ports from which to choose, how does a client know which port to use when requesting a service? The term **well-known port number** is often used when describing popular services on the Internet, such as Web servers and e-mail servers. All Web browsers know 80 as the well-known port on a Web server where requests for HTML documents are made. So when you type a URL into a Web browser, the browser by default connects to port 80 on the server. Because, the Tomcat server uses port 8080 as its

port number, requests to Tomcat for Web pages or to invoke servlets and JavaServer Pages must specify that the Tomcat server listens on port 8080.

The client can access the servlet only if it is installed on a server that can respond to servlet requests. In some cases, servlet support is built directly into the Web server, and no special configuration is required to handle servlet requests. In other cases, it is necessary to integrate a servlet container with a Web server (as can be done with Tomcat and the Apache or IIS Web servers). Web servers that support servlets normally have an installation procedure for servlets. If you intend to execute your servlet as part of a Web server, please refer to your server's documentation on how to install a servlet. For our examples, we demonstrate servlets with the Apache Tomcat server. [Section 26.3](#) discusses the setup and configuration of Tomcat for use with this chapter. [Section 26.4.1](#) discusses the deployment of the servlet in [Fig. 26.7](#).

### 26.4.1. Deploying a Web Application

JSPs, servlets and their supporting files are deployed as part of [Web applications](#). Normally, Web applications are deployed in the `webapps` subdirectory of `jakarta-tomcat-5.0.25`. A Web application has a well-known directory structure in which all the files that are part of the application reside. This structure can be created by the server administrator in the `webapps` directory, or the entire directory structure can be archived in a [Web application archive file](#). Such an archive is known as a [WAR file](#) and ends with the `.war` file extension. Such files are typically placed in the `webapps` directory. When the Tomcat server begins execution, it extracts the WAR file's contents into the appropriate `webapps` subdirectory structure. For simplicity as we teach servlets and JavaServer Pages, we create the already expanded directory structure for all the examples in this chapter.

The Web application directory structure contains a [context root](#)the top-level directory for an entire Web applicationand several subdirectories. These are described in [Fig. 26.9](#).

Figure 26.9. Web application standard directories.

(This item is displayed on page 1252 in the print version)

| Directory                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| context root                 | This is the root directory for the Web application. All the JSPs, HTML documents, servlets and supporting files such as images and class files reside in this directory or its subdirectories. The name of this directory is specified by the Web application creator. To provide structure in a Web application, subdirectories can be placed in the context root. For example, if your application uses many images, you might place an <code>images</code> subdirectory in this directory. The examples of this chapter use <code>jhttp6</code> as the context root. |
| <code>WEB-INF</code>         | This directory contains the Web application deployment descriptor ( <code>web.xml</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>WEB-INF/classes</code> | This directory contains the servlet class files and other supporting class files used in a Web application. If the classes are part of a package, the complete package directory structure would begin here.                                                                                                                                                                                                                                                                                                                                                            |
| <code>WEB-INF/lib</code>     | This directory contains Java archive (JAR) files. The JAR files can contain servlet class files and other supporting class files used in a Web application.                                                                                                                                                                                                                                                                                                                                                                                                             |

## Common Programming Error 26.1

*Using "servlet" or "servlets" as a context root may prevent a servlet from working correctly on some servers. x*

Configuring the context root for a Web application in Tomcat requires creating a subdirectory in the `webapps` directory. When Tomcat begins execution, it creates a context root for each subdirectory of `webapps`, using each subdirectory's name as a context root name. To test the examples in this chapter, create the directory `jhttp6` in Tomcat's `webapps` directory.

After configuring the context root, we must configure our Web application to handle the requests. This configuration occurs in a [deployment descriptor](#), which is stored in a file called `web.xml`. This specifies various configuration parameters, such as the name used to invoke the servlet (i.e., its alias), a description of the servlet, the servlet's fully qualified class name and a [servlet mapping](#) (i.e., the path or paths that cause the servlet container to invoke the servlet). You must create the `web.xml` file for this example. Many Java Web application deployment tools create the `web.xml` file for you. The one for the first example in this chapter is shown in [Fig. 26.10](#). We will enhance this file as we add other servlets to the Web application throughout this chapter.

Figure 26.10. Deployment descriptor (`web.xml`) for the `jhttp6` Web application.

---

[Page 1252]

Element **web-app** (lines 137) defines the configuration of each servlet in the Web application and the servlet mapping for each servlet. Element **display-name** (lines 811) specifies a name that can be displayed to the administrator of the server on which the Web application is installed. Element **description** (lines 1316) specifies a description of the Web application that might be displayed to the server administrator.

Element **servlet** (lines 1929) describes a servlet. Element **servlet-name** (line 20) is the name we chose for the servlet (**welcome1**). Element **description** (lines 2224) specifies a description for this particular servlet. Again, this can be displayed to the server administrator. Element **servlet-class** (lines 2628) specifies the compiled servlet's fully qualified class name. Thus, the servlet **welcome1** is defined by class **WelcomeServlet**.

Element **servlet-mapping** (lines 3235) specifies **servlet-name** and **url-pattern** elements. The **URL pattern** helps the server determine which requests are sent to the servlet (**welcome1**). Our Web application will be installed as part of the **jhttp6** context root discussed in [Section 26.4.1](#). Thus, the relative URL we supply to the browser to invoke the servlet in this example is

```
/jhttp6/welcome1
```

where **/jhttp6** specifies the context root that helps the server determine which Web application handles the request and **/welcome1** specifies the URL pattern that is mapped to servlet **welcome1** to handle the request. Note that the server on which the servlet resides is not specified here, although this can be done as follows:

```
http://localhost:8080/jhttp6/welcome1
```

---

[Page 1253]

If the explicit server and port number are not specified as part of the URL, the browser assumes that the form handler (i.e., the value of the **action** attribute of the **form** element in HTML) resides at the same server and port number from which the browser downloaded the Web page containing the **form**.

There are several URL pattern formats that can be used. The **/welcome1** URL pattern requires an exact match of the pattern. You can also specify **path mappings**, **extension mappings** and a **default servlet** for a Web application. A path mapping begins with a **/** and ends with a **/\***. For example, the URL pattern

```
/jhttp6/example/*
```

---

[Page 1254]

indicates that any URL path beginning with **/jhttp6/example/** will be sent to the servlet that has the preceding URL pattern. An extension mapping begins with **\***. and ends with a file-name extension. For

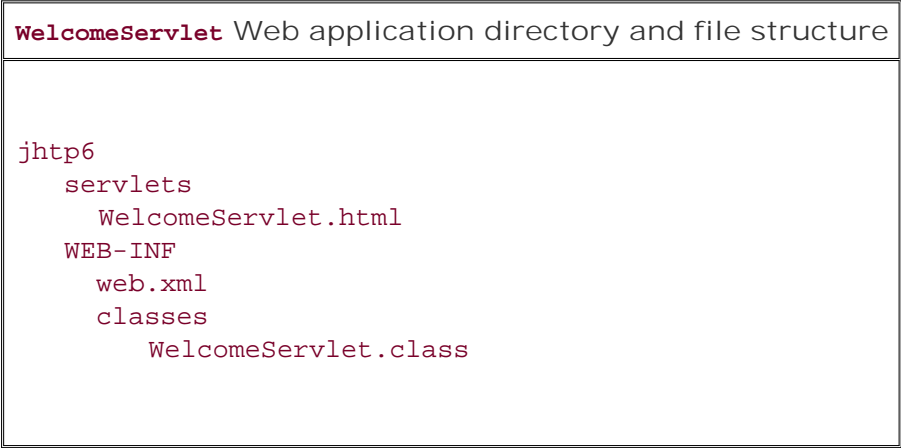

example, the URL pattern

`*.jsp`

indicates that any request for a file with extension `.jsp` will be sent to the servlet that handles JSP requests. In fact, servers with JSP containers have an implicit mapping of the `.jsp` extension to a servlet that handles JSP requests. The URL pattern `/` represents the default servlet for the Web application. This is similar to the default document of a Web server. For example, if you type the URL [www.deitel.com](http://www.deitel.com) into your Web browser, the document you receive from our Web server is the default document `index.html`. If the URL pattern matches the default servlet for a Web application, that servlet is invoked to return a default response to the client. This can be useful for personalizing Web content to specific users. To compile your servlet, you will need to use `javac`'s `-classpath` option to specify the name and location of the file `servlet-api.jar`, which is located in Tomcat's `common\libs` directory. Finally, we are ready to place our files into the appropriate directories to complete the deployment of our first servlet for testing. We have three files to place `WelcomeServlet.html`, `WelcomeServlet.class` and `web.xml`. In your `jakarta-tomcat-5.0.25\webapps\jhttp6` directory the context root for our Web application create subdirectories named `servlets` and `WEB-INF`. We place our HTML files for this servlets chapter in the `servlets` directory. Copy the `WelcomeServlet.html` file into the `servlets` directory. In the `WEB-INF` directory, create the subdirectory `classes`, then copy the `web.xml` file into the `WEB-INF` directory, and copy the `WelcomeServlet.class` file into the `classes` directory. Thus, the directory and file structure under the `webapps` directory should be as shown in [Fig. 26.11](#) (file names are in italics). After the files are placed in the proper directories, start the Tomcat server, open your browser and type the following URL

`http://localhost:8080/jhttp6/servlets/WelcomeServlet.html`

Figure 26.11. Web application directory and file structure for `WelcomeServlet`.

to load `WelcomeServlet.html` into the Web browser. Then click the **Get HTML Document** button to invoke the servlet. You should see the results shown in [Fig. 26.8](#). You can try this servlet from several different Web browsers to demonstrate that the results are the same across Web browsers.

## Common Programming Error 26.2

*Not placing a servlet or other class files in the appropriate directory structure prevents the server from locating those classes properly. This results in an error response to the client Web browser.*

Actually, the HTML file in [Fig. 26.8](#) was not necessary to invoke this servlet. A `get` request can be sent to a server simply by typing the URL in a browser exactly as you do when you request a Web page in the browser. In this example, you can type

```
http://localhost:8080/jhttp6/welcome1
```

in the **Address** or **Location** field of your browser to invoke the servlet directly.

## Error-Prevention Tip 26.3

*You can test a servlet that handles HTTP get requests by typing the URL that invokes the servlet directly into your browser's **Address** or **Location** field because get is the default HTTP method when browsing.*

## 26.5. Handling HTTP **get** Requests Containing Data

When requesting a document or resource from a Web server, it is possible to supply data as part of the request. The servlet `WelcomeServlet2` in [Fig. 26.12](#) responds to an HTTP **get** request that contains a name supplied by the user. The servlet uses the name as part of the response to the client.

Figure 26.12. `WelcomeServlet2` responds to a **get** request containing data.

(This item is displayed on page 1256 in the print version)

```
1 // Fig. 26.12: WelcomeServlet2.java
2 // Processing HTTP get requests containing data.
3 import javax.servlet.ServletException;
4 import javax.servlet.http.HttpServlet;
5 import javax.servlet.http.HttpServletRequest;
6 import javax.servlet.http.HttpServletResponse;
7 import java.io.IOException;
8 import java.io.PrintWriter;
9
10 public class WelcomeServlet2 extends HttpServlet
11 {
12 // process "get" request from client
13 protected void doGet(HttpServletRequest request,
14 HttpServletResponse response)
15 throws ServletException, IOException
16 {
17 String firstName = request.getParameter("firstname");
18
19 response.setContentType("text/html");
20 PrintWriter out = response.getWriter();
21
22 // send XHTML document to client
23
24 // start XHTML document
25 out.println("<?xml version = \"1.0\"?>");
26
27 out.printf("%s%s%s" , "<!DOCTYPE html PUBLIC" ,
28 " \"-//W3C//DTD XHTML 1.0 Strict//EN\"",
29 "\"http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd\">\n");
30
31 out.println("<html xmlns = \"http://www.w3.org/1999/xhtml\">");
32
33 // head section of document
34 out.println("<head>");
35 out.println(
36 "<title>Processing get requests with data</title>");
37 out.println("</head>");
38
39 // body section of document
40 out.println("<body>");
41 out.println("<h1>Hello " + firstName + ",
");
42 out.println("Welcome to Servlets!</h1>");
```

```

43 out.println("</body>");
44
45 // end XHTML document
46 out.println("</html>");
47 out.close(); // close stream to complete the page
48 } // end method doGet
49 } // end class WelcomeServlet2

```

Parameters are passed as name-value pairs in a `get` request. Line 17 demonstrates how to obtain information that was passed to the servlet as part of the client request. The `request` object's `getParameter` method accepts the parameter name as an argument and returns the corresponding `String` value, or `null` if the parameter is not part of the request. Note that parameter names are case sensitive and must match exactly. Line 41 uses the result of line 17 as part of the response to the client.

The `WelcomeServlet2.html` document ([Fig. 26.13](#)) provides a `form` in which the user can input a name in the text `input` element `firstname` (line 16) and click the **Submit** button to invoke `WelcomeServlet2`. When the user presses the **Submit** button, the values of the `input` elements are placed in name-value pairs as part of the request to the server. In the second screen capture in [Fig. 26.13](#), note that the browser appended

```
?firstname=Jon
```

to the end of the `action` URL. The `?` separates the `query string` (i.e., the data passed as part of the `get` request) from the rest of the URL in a `get` request. The name-value pairs are passed with the name and the value separated by `=`. If there is more than one namevalue pair, each pair is separated by `&`.

Figure 26.13. HTML document in which the form's `action` invokes `WelcomeServlet2` through the alias `welcome2` specified in `web.xml`.

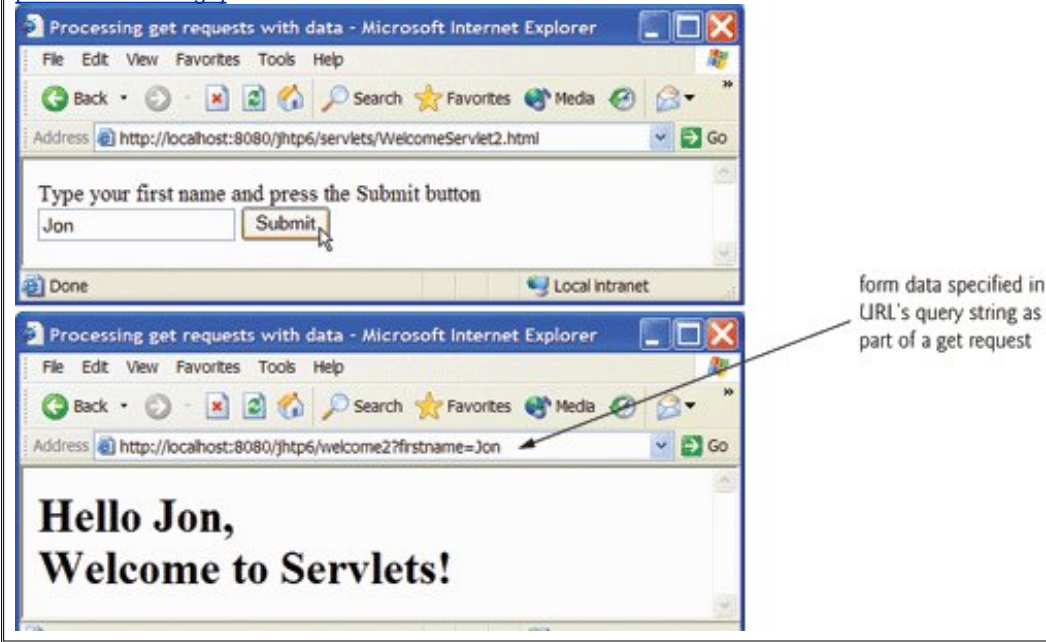

(This item is displayed on page 1257 in the print version)

```

1 <?xml version = "1.0"?>
2 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"
3 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">
4
5 <!-- Fig. 26.13: WelcomeServlet2.html -->
6
7 <html xmlns = "http://www.w3.org/1999/xhtml">
8 <head>
9 <title>Processing get requests with data </title>
10 </head>
11
12 <body>
13 <form action = "/jhttp6/welcome2" method = "get" >
14 <p><label>
15 Type your first name and press the Submit button
16
<input type = "text" name = "firstname" />
17 <input type = "submit" value = "Submit" />
18 </p></label>
19 </form>
20 </body>
21 </html>

```

[View full size image](#)

Once again, we use our `jhttp6` context root to demonstrate the servlet of [Fig. 26.12](#). Place `WelcomeServlet2.html` in the `servlets` directory created in [Section 26.4.1](#). Place `WelcomeServlet2.class` in the `classes` subdirectory of `WEB-INF` in the `jhttp6` context root. Remember that classes in a package must be placed in the appropriate package directory structure. Then edit the `web.xml` deployment descriptor in the `WEB-INF` directory to include the information specified in [Fig. 26.14](#). This table contains the information for the `servlet` and `servlet-mapping` elements that you will add to the `web.xml` deployment descriptor. You should not type the italic text into the deployment descriptor. Restart Tomcat and type the following URL in your Web browser:

[Page 1256]

[Page 1257]

`http://localhost:8080/jhttp6/servlets/WelcomeServlet2.html`

Figure 26.14. Deployment descriptor information for servlet `WelcomeServlet2`.

| <code>servlet-class</code>     | <code>WelcomeServlet2</code>          |
| <i>servlet-mapping element</i> |                                       |
| <code>servlet-name</code>      | <code>welcome2</code>                 |

| Descriptor element | Value     |
|--------------------|-----------|
| url-pattern        | /welcome2 |

Type your name in the text field of the Web page, then click Submit to invoke the servlet. Once again, note that the `get` request could have been typed directly into the browser's Address or Location field as follows:

```
http://localhost:8080/jhttp6/welcome2?firstname=Jon
```

---

[Page 1258]

## Error-Prevention Tip 26.4

*If an error occurs during the servlet invocation, the log files in the `logs` directory of the Tomcat installation can help you determine the error and debug the problem.*

## Software Engineering Observation 26.4

*A `get` request is limited to standard characters, which means that you cannot submit any special characters via a `get` request. The length of the URL in a `get` request is limited. For example, the maximum URL length in Internet Explorer is 2,083 characters. Some Web servers might restrict this even more.*

## Good Programming Practice 26.1

*A `get` request should not be used for sending sensitive data (e.g., a password) because the form data is placed in a query string that is appended to the request URL as plain text and can be intercepted.*

## 26.6. Handling HTTP `post` Requests

An HTTP `post` request is frequently used to send data from an HTML form to a server-side form handler that processes the data. For example, when you respond to a Web-based survey, a `post` request normally supplies the information you type in the form to the Web server.

Browsers often cache (save on disk) Web pages so they can quickly reload them. If there are no changes between the last version stored in the cache and the current version on the Web, this helps speed up your browsing experience. The browser first asks the server whether the document has changed or expired since the date the file was cached. If not, the browser loads the document from the cache. Thus, the browser minimizes the amount of data that must be downloaded for you to view a Web page. Browsers typically do not cache the server's response to a `post` request, because the next `post` might not return the same result. For example, in a survey, many users could visit the same Web page and respond to a question. The survey results could then be displayed for the user. Each new response changes the overall results of the survey.

When you use a Web-based search engine, the browser normally supplies the information you specify in an HTML form to the search engine with a `get` request. The search engine performs the search, then returns the results to you as a Web page. Such pages are often cached by the browser in case you perform the same search again. As with `post` requests, `get` requests can supply parameters as part of the request to the Web server.

---

[Page 1259]

The `WelcomeServlet3` servlet in [Fig. 26.15](#) is identical to the servlet in [Fig. 26.12](#), except that it defines a `doPost` method (lines 1348) rather than a `doGet` method to respond to `post` requests. The default functionality of `doPost` is to indicate a "Method not supported" error. We override this method to provide custom `post` request processing. Method `doPost` accepts the same two arguments as `doGet`: an object that implements interface `HttpServletRequest` to represent the client's request and an object that implements interface `HttpServletResponse` to represent the servlet's response. As with `doGet`, method `doPost` throws a `ServletException` if it is unable to handle a client's request and throws an `IOException` if a problem occurs during stream processing.

Figure 26.15. `WelcomeServlet3` responds to a `post` request containing data.

(This item is displayed on pages 1259 - 1260 in the print version)

```

1 // Fig. 26.15: WelcomeServlet3.java
2 // Processing post requests containing data.
3 import javax.servlet.ServletException;
4 import javax.servlet.http.HttpServlet;
5 import javax.servlet.http.HttpServletRequest;
6 import javax.servlet.http.HttpServletResponse;
7 import java.io.IOException;
8 import java.io.PrintWriter;
9
10 public class WelcomeServlet3 extends HttpServlet
11 {
12 // process "post" request from client
13 protected void doPost(HttpServletRequest request,
14 HttpServletResponse response)
15 throws ServletException, IOException
16 {
17 String firstName = request.getParameter("firstname");
18
19 response.setContentType("text/html");
20 PrintWriter out = response.getWriter();
21
22 // send XHTML page to client
23
24 // start XHTML document
25 out.println("<?xml version = \"1.0\"?>");
26
27 out.printf("%s%s%s" , "<!DOCTYPE html PUBLIC" ,
28 " \"-//W3C//DTD XHTML 1.0 Strict//EN\"",
29 " \"http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd\">\n");
30
31 out.println("<html xmlns = \"http://www.w3.org/1999/xhtml\">");
32
33 // head section of document
34 out.println("<head>");
35 out.println(
36 "<title>Processing post requests with data</title>");
37 out.println("</head>");
38
39 // body section of document
40 out.println("<body>");
41 out.println("<h1>Hello " + firstName + ",
");
42 out.println("Welcome to Servlets!</h1>");
43 out.println("</body>");
44
45 // end XHTML document
46 out.println("</html>");
47 out.close(); // close stream to complete the page
48 } // end method doPost
49 } // end class WelcomeServlet3

```

`WelcomeServlet3.html` (Fig. 26.16) provides a `form` (lines 1319) in which the user can input a name in the text input element `firstname` (line 16), then click the **Submit** button to invoke `WelcomeServlet3`. When the user presses the **Submit** button, the values of the `input` elements are sent to the server as part of the request. However, note that the values are not appended to the request URL. The form's `method` in this example is `post`, but note that a `post` request cannot be typed into the browser's **Address** or **Location** field,

and users cannot bookmark `post` requests in their browsers.

We use our `jhttp6` context root to demonstrate the servlet in [Fig. 26.15](#). Place `WelcomeServlet3.html` in the `servlets` directory created in [Section 26.4.1](#). Place `WelcomeServlet3.class` in the `classes` subdirectory of `WEB-INF` in the `jhttp6` context root. Then, using the information specified in [Fig. 26.17](#), edit the `web.xml` deployment descriptor in the `WEB-INF` directory. Restart Tomcat and type the following URL in your Web browser:

---

[Page 1261]

`http://localhost:8080/jhttp6/servlets/WelcomeServlet3.html`

Type your name in the text field of the Web page, then click Submit to invoke the servlet.

Figure 26.16. HTML document in which the form's `action` invokes `WelcomeServlet3` through the alias `welcome3` specified in `web.xml`.

(This item is displayed on pages 1260 - 1261 in the print version)

```
1 <?xml version = "1.0"?>
2 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"

## 26.7. Redirecting Requests to Other Resources

Sometimes it is useful to redirect a request to a different resource. For example, a servlet could determine the type of the client browser and redirect the request to a Web page that was designed specifically for that browser. This technique is also used to redirect browsers to an error page when handling a request fails. The `RedirectServlet` in [Fig. 26.18](#) receives a `page` parameter as part of a `get` request, then uses that parameter to redirect the request to a different resource.

---

[Page 1262]

Figure 26.18. Redirecting requests to other resources.

(This item is displayed on pages 1262 - 1263 in the print version)

```
1 // Fig. 26.18: RedirectServlet.java
2 // Redirecting a user to a different Web page.
3 import javax.servlet.ServletException;
4 import javax.servlet.http.HttpServlet;
5 import javax.servlet.http.HttpServletRequest;
6 import javax.servlet.http.HttpServletResponse;
7 import java.io.IOException;
8 import java.io.PrintWriter;
9
10 public class RedirectServlet extends HttpServlet
11 {
12 // process "get" request from client
13 protected void doGet(HttpServletRequest request,
14 HttpServletResponse response)
15 throws ServletException, IOException
16 {
17 String location = request.getParameter("page");
18
19 if (location != null)
20 {
21 if (location.equals("deitel"))
22 response.sendRedirect("http://www.deitel.com");
23 else if (location.equals("welcome1"))
24 response.sendRedirect("welcome1");
25 } // end if
26
27 // code that executes only if this servlet
28 // does not redirect the user to another page
29 response.setContentType("text/html");
30 PrintWriter out = response.getWriter();
31
32 // start XHTML document
33 out.println("<?xml version = \"1.0\"?>");
34
35 out.printf("%s%s%s" , "<!DOCTYPE html PUBLIC" ,
36 " \"-//W3C//DTD XHTML 1.0 Strict//EN\"",
37 "\"http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd\">\n");
38 }
```

```

39 out.println(
40 "<html xmlns = \"http://www.w3.org/1999/xhtml\">");
41
42 // head section of document
43 out.println("<head>");
44 out.println("<title>Invalid page</title>");
45 out.println("</head>");
46
47 // body section of document
48 out.println("<body>");
49 out.println("<h1>Invalid page requested</h1>");
50 out.println("<p><a href = " +
51 "\"servlets/RedirectServlet.html\">");
52 out.println("Click here to choose again</p>");
53 out.println("</body>");
54
55 // end XHTML document
56 out.println("</html>");
57 out.close(); // close stream to complete the page
58 } // end method doGet
59 } // end class RedirectServlet

```

Line 17 obtains the `page` parameter from the request. If the value returned is not `null`, the nested `if...else if` statement at lines 2124 determines whether the value is either `"deitel"` or `"welcome1"`. If the value is `"deitel"`, the `response` object's `sendRedirect` method (line 22) redirects the request to [www.deitel.com](http://www.deitel.com). If the value is `"welcome1"`, line 24 redirects the request to the servlet of [Fig. 26.7](#). Note that line 24 does not explicitly specify the `jhttp6` context root for our Web application. When a servlet uses a relative path to reference another static or dynamic resource, the servlet assumes the same base URL and context root as the one that invoked the servlet unless a complete URL is specified for the resource. So line 24 actually is requesting the resource located at

---

[Page 1263]

`http://localhost:8080/jhttp6/welcome1`

Similarly, line 51 is actually requesting the resource located at

`http://localhost:8080/jhttp6/servlets/RedirectServlet.html`

## Software Engineering Observation 26.5

*Using relative paths to reference resources in the same context root makes your Web application more flexible. For example, you can change the context root without making changes to the static and dynamic resources in the application.*

Once method `sendRedirect` executes, processing of the original request by the `RedirectServlet` terminates.

If method `sendRedirect` is not called, the remainder of method `doGet` outputs a Web page indicating that an invalid request was made. The page allows the user to try again by returning to the XHTML document of [Fig. 26.19](#). Note that one of the redirects is sent to a static XHTML Web page and the other is sent to a servlet.

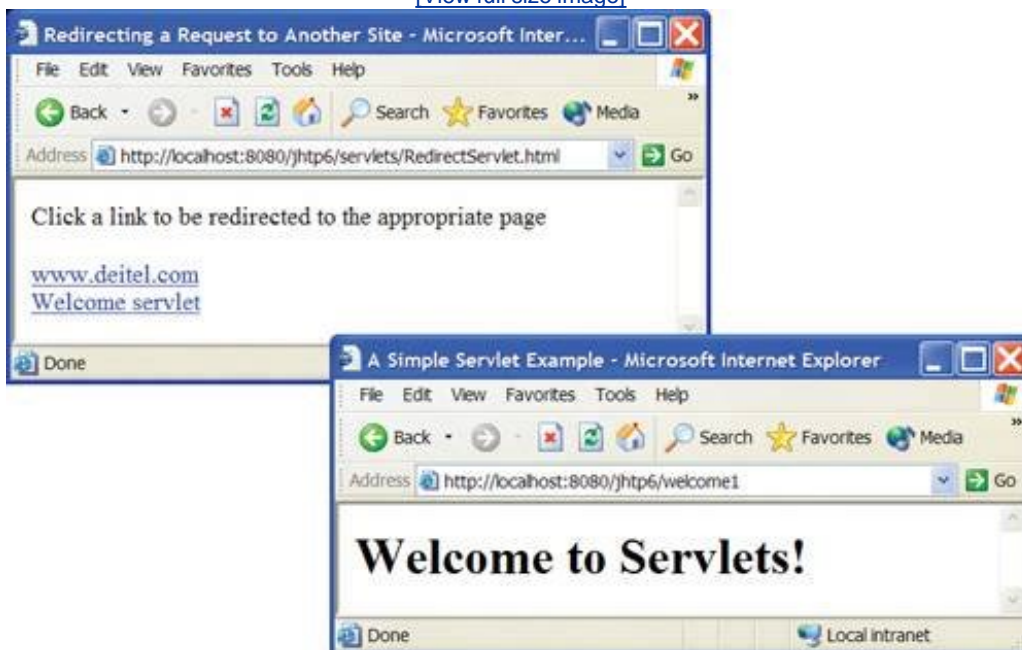

Figure 26.19. `RedirectServlet.html` document to demonstrate redirecting requests to other resources.

(This item is displayed on page 1264 in the print version)

```
1 <?xml version = "1.0" ?>
2 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"
3 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">
4
5 <!-- Fig. 26.19: RedirectServlet.html -->
6
7 <html xmlns = "http://www.w3.org/1999/xhtml">
8 <head>
9 <title>Redirecting a Request to Another Site</title>
10 </head>
11
12 <body>
13 <p>Click a link to be redirected to the appropriate page</p>
14 <p>
15
16 www.deitel.com

17
18 Welcome servlet
19 </p>
20 </body>
21 </html>
```

[\[View full size image\]](#)

`RedirectServlet.html` (Fig. 26.19) provides two links (lines 1516 and 1718) that allow the user to invoke the servlet `RedirectServlet`. Each link specifies a `page` parameter as part of the URL. To demonstrate passing an invalid page, you can type the URL into your browser with no value for the `page` parameter.

We use our `jhttp6` context root to demonstrate the servlet of Fig. 26.18. Place `RedirectServlet.html` in the `servlets` directory created in Section 26.4.1. Place `Redirect-Servlet.class` in the `classes` subdirectory of `WEB-INF` in the `jhttp6` context root. Then, edit the `web.xml` deployment descriptor in the `WEB-INF` directory to include the information specified in Fig. 26.20. Restart Tomcat, and type the following URL in your Web browser:

```
http://localhost:8080/jhttp6/servlets/RedirectServlet.html
```

Click a link in the Web page to invoke the servlet.

Figure 26.20. Deployment descriptor information for servlet `RedirectServlet`.

(This item is displayed on page 1265 in the print version)

| Descriptor element             | Value                                               |
|--------------------------------|-----------------------------------------------------|
| <i>servlet element</i>         |                                                     |
| <code>servlet-name</code>      | <code>redirect</code>                               |
| <code>description</code>       | Redirecting to static Web pages and other servlets. |
| <code>servlet-class</code>     | <code>RedirectServlet</code>                        |
| <i>servlet-mapping element</i> |                                                     |
| <code>servlet-name</code>      | <code>redirect</code>                               |
| <code>url-pattern</code>       | <code>/redirect</code>                              |

When redirecting requests, the request parameters from the original request are passed as parameters to the new request. Additional request parameters can also be passed. For example, the URL passed to `sendRedirect` could contain name-value pairs. New parameters are added to the existing parameters. A new parameter with the same name as an existing parameter takes precedence over the original value. However, all the values are still passed. In this case, the complete set of values for a given parameter name can be obtained by calling method `getParameterValues` from interface `HttpServletRequest`. This method accepts the parameter name as an argument and returns an array of strings containing the parameter values in most-recent-to-least-recent-order.

## 26.8. Multitier Applications: Using JDBC from a Servlet

Servlets can communicate with databases via JDBC ([Chapter 25](#)). Many of today's applications are [three-tier distributed applications](#), consisting of a [user interface](#), [business logic](#) and a [database](#). The user interface in such an application is often created using HTML or XHTML (as shown in this chapter). HTML and XHTML are preferred in systems where portability is a concern. Using the networking provided by the browser, the user interface can communicate with the middle-tier business logic. The middle tier can then access the database to manipulate the data. The three tiers can reside on separate computers that are connected to a network.

In multitier architectures, Web servers often are used in the middle tier. Server-side components, such as servlets, execute in an application server alongside the Web server. These components provide the business logic that manipulates data from databases and communicates with client Web browsers. Servlets, through JDBC, can interact with popular database systems. Developers use SQL for queries, and JDBC drivers handle the specifics of interacting with each database system.

The [SurveyServlet](#) in [Fig. 26.21](#) and the [Survey.html](#) document in [Fig. 26.22](#) implement portions of a three-tier distributed application. The middle tier is [SurveyServlet](#), which handles requests from the client browser and provides access to the third tier MySQL database accessed via JDBC. The servlet in this example allows users to vote for their favorite animals. When the servlet receives a [post](#) request from the Web browser, the servlet uses JDBC to update the total number of votes for that animal in the database and returns a dynamically generated XHTML document containing the survey results to the client.

Figure 26.21. Multitier Web-based survey using XHTML, servlets and JDBC.

(This item is displayed on pages 1266 - 1268 in the print version)

```
1 // Fig. 26.21: SurveyServlet.java

27 <p><input type = "submit" value = "Submit" /></p>
28 </form>
29 </body>
30 </html>

```

[\[View full size image\]](#)

Lines 21 and 22 begin by declaring a `Connection` to manage the database connection and a `Statement` for updating the vote count for an animal, totaling all the votes and obtaining the complete survey results.

[Page 1269]

Servlets are initialized by method `init`, which we override in `SurveyServlet` (lines 2546). Method `init` is called exactly once in a servlet's life cycle, before any client requests are accepted. The method takes `ServletConfig` argument and throws a `Servlet-Exception`. The argument provides the servlet with information about its `initialization parameters` (i.e., parameters not associated with a request, but passed to the servlet for initializing the servlet). These parameters are specified in the `web.xml` deployment descriptor file as part of a `servlet` element. Each parameter appears in an `init-param` element of the following form:

```

<init-param>
 <param-name>parameter name</param-name>
 <param-value>parameter value </param-value>
</init-param>

```

Servlets can obtain initialization parameter values by invoking `ServletConfig` method `getInitParameter`, which receives a string representing the `param-name` of the parameter and returns the `param-value` as a string.

In this example, the servlet's `init` method (lines 2546) performs the connection to the MySQL database. Line 30 loads the driver (`com.mysql.jdbc.Driver`, which is specified in the initialization parameter `"databaseDriver"`). Lines 3134 attempt to open a connection to the `animalsurvey` database. The database name, username and password are specified in the initialization parameters `"databaseName"`, `"username"` and `"password"`, respectively. The database contains one table (`surveyresults`) that consists of three fields: a unique integer to identify each record (`id`), a string representing the survey option (`surveyoption`) and an integer representing the number of votes for a survey option (`votes`). [Note: The examples folder for this chapter contains the SQL script `animalsurvey.sql` with which you can create the `animalsurvey` database for this example. For information on executing the SQL script, please refer to [Chapter 25](#).]

When a user submits a survey response, method `doPost` (lines 49132) handles the request. Lines 7172 obtain the survey response, then lines 76121 attempt to process it. Lines 7980 specify an update statement to increment the `votes` value for the record with the specified ID and update the database. Lines 8587 execute the query specified in line 84 to retrieve the total number of votes received using SQL's built-in `sum` function to total all the votes in the `surveyresults` table. Then lines 92120 execute the query specified in lines 9091 to obtain the data in the table and process the `ResultSet` to create the survey summary for the client. When the servlet container terminates the servlet, method `destroy` (lines 135148) closes the `Statement`, then closes the database connection. [Figure 26.22](#) shows `survey.html`, which invokes `SurveyServlet` through alias `animalsurvey` when the user submits the form.

We use our `jhttp6` context root to demonstrate the servlet of [Fig. 26.21](#). Place `Survey.html` in the `servlets` directory created previously. Place `SurveyServlet.class` (with the complete package structure) in the `classes` subdirectory of `WEB-INF` in the `jhttp6` context root. Then, edit the `web.xml` deployment descriptor in the `WEB-INF` directory to include the information specified in [Fig. 26.23](#). This program cannot execute in Tomcat unless the Web application has access to the JAR file that contains the MySQL database driver and its supporting classes. This JAR file (`mysql-connector-java-3.0.14-production-bin.jar`) can be found in your MySQL Connector's installation directory. Place a *copy* of this file in the `WEB-INF` subdirectory `lib` to make its contents available to the Web application. Please refer to [Chapter 25](#) for more information on how to configure MySQL.

Figure 26.23. Deployment descriptor information for servlet **SurveyServlet**.

(This item is displayed on page 1272 in the print version)

| Descriptor element         | Value                                                 |

| <code>init-param</code>        |                                                  |
| <code>param-name</code>        | <code>username</code>                            |
| <code>param-value</code>       | <code>jhttp6</code>                              |
| <code>init-param</code>        |                                                  |
| <code>param-name</code>        | <code>password</code>                            |
| <code>param-value</code>       | <code>jhttp6</code>                              |
| <i>servlet-mapping element</i> |                                                  |
| <code>servlet-name</code>      | <code>animalsurvey</code>                        |
| <code>url-pattern</code>       | <code>/animalsurvey</code>                       |

After copying these files, type the following URL in your Web browser:

`http://localhost:8080/jhttp6/servlets/Survey.html`

Select an animal and press the **Submit** button to invoke the servlet. [ *Note:* The MySQL database server should be running when the servlet is invoked.]

## 26.9. Welcome Files

Web application developers can specify an ordered list of **welcome files** to be loaded when the request URL is not mapped to a servlet. These files are typically HTML or JSP documents. Welcome files are defined using the **welcome-file-list** element in the deployment descriptor. Element **welcome-file-list** contains one or more **welcome-file** elements. Each **welcome-file** element specifies the partial URL of a welcome file without a leading or trailing `/`. For example, the following **welcome-file-list** element indicates that `index.html` and `index.htm` are the welcome files.

```
<welcome-file-list>
 <welcome-file>index.html</welcome-file>
 <welcome-file>index.htm</welcome-file>
</welcome-file-list>
```

---

[Page 1271]

To specify the welcome files for the `jhttp6` context root, insert the preceding **welcomefile-list** element after the last **servlet-mapping** element in the `web.xml` deployment descriptor. When the URL `http://localhost:8080/jhttp6/` is requested, the Web server appends each welcome file in the order specified in the deployment descriptor to the request URL, such as

---

[Page 1272]

```
http://localhost:8080/jhttp6/index.html
http://localhost:8080/jhttp6/index.htm
```

and checks whether the resource is valid. The servlet container sends the request to the first matching welcome file. For example, if `index.html` exists in the `jhttp6` directory, the servlet container sends the request to the `http://localhost:8080/jhttp6/index.html`. If no matching welcome file is found, the servlet container returns a response indicating that the resource is not available.

[Figure 26.24](#) is the `index.html` that provides links (lines 1524) to test all the examples demonstrated in this chapter. Copy this file to `C:\jakarta-tomcat-5.0.25\webapps\jhttp6` and restart the Tomcat server. To test the welcome file, type the following URL in your Web browser:

Figure 26.24. Welcome file **index.html**.

(This item is displayed on page 1273 in the print version)

```

1 <?xml version = "1.0" ?>

## 26.10. Wrap-Up

This chapter continued our networking discussions by presenting servlets that enhance the functionality of Web servers. You learned the architecture and life cycle of servlets. You learned how to respond to HTTP requests by using an `HttpServlet`. You also learned how to redirect requests to a static or dynamic Web resource. You executed the sample servlets with the Apache Tomcat server. You then built a multitier Web application that uses JDBC to access and manipulate a database from a servlet. In the next chapter, we introduce JavaServer Pagesan extension of servlet technology. We demonstrate several JSP componentsimplicit objects, scripting elements, standard actions and directives. We also discuss how to use `CachedRowSets` to access a MySQL database from a JavaBean object, then access the JavaBean object from a JSP page.

## 26.11. Internet and Web Resources

This section lists a variety of servlet resources available on the Internet and provides a brief description of each.

[java.sun.com/products/servlet/index.html](http://java.sun.com/products/servlet/index.html)

The servlet page at the Sun Microsystems, Java Web site provides access to the latest servlet information and servlet resources.

[jakarta.apache.org](http://jakarta.apache.org)

This is the Apache Project's home page for the *Jakarta Project*.

[jakarta.apache.org/tomcat/index.html](http://jakarta.apache.org/tomcat/index.html)

Home page for the Tomcat servlets and JavaServer Pages reference implementation.

[www.servlets.com](http://www.servlets.com)

This Web site provides news, tools and documents for servlets and JSP technologies. It also links to the book *Java Servlet Programming* published by O'Reilly.

[theserverside.com](http://theserverside.com)

*TheServerSide.com* is dedicated to information and resources for J2EE.

[www.javacorporate.com/expresso/frame.jsp](http://www.javacorporate.com/expresso/frame.jsp)

Home of the open-source *Expresso Framework*, which includes a library of extensible servlet components to help speed Web application development.

[www.servlet.com/srvdev.jhtml](http://www.servlet.com/srvdev.jhtml)

*ServletInc's Servlet Developers Forum* provides resources for server-side Java developers and information about Web servers that support servlet technologies.

[www.coolservlets.com](http://www.coolservlets.com)

Provides free open-source Java servlets.

[www.cetus-links.org/oo\\_java\\_servlets.html](http://www.cetus-links.org/oo_java_servlets.html)

Provides a list of links to resources on servlets and other technologies.

[www.javaskyline.com](http://www.javaskyline.com)

*Java Skyline* is an online magazine for servlet developers.

[www.rfc-editor.org](http://www.rfc-editor.org)

The RFC Editor provides a search engine for RFCs (Requests for Comments). Many of these RFCs provide details of Web-related technologies. RFCs of interest to servlet developers include *URI in WWW* (RFC 1630), *URI: generic syntax* (RFC 2396), *HTTP State Management Mechanism* (RFC 2109), *Use and Interpretation of HTTP Version Numbers* (RFC 2145), *Hyper Text Coffee Pot Control Protocol* (RFC 2324), HTTP/1.1 (RFC 2616) and *HTTP Authentication: Basic and Digest Authentication* (RFC 2617).

# Summary

- The classes and interfaces used to define servlets are found in packages `javax.servlet` and `javax.servlet.http`.
- URLs represent files or directories and can represent complex tasks, such as database lookups and Internet searches.
- JavaServer Pages technology, an extension of servlet technology, simplifies the process of creating pages by separating presentation from content.
- Servlets are normally executed by the servlet container component of a Web application server.
- All servlets must implement the `Servlet` interface. The methods of interface `Servlet` are invoked automatically by the servlet container.
- A servlet's life cycle begins when the servlet container loads the servlet into memory normally in response to the first request to that servlet. Before the servlet can handle the first request, the servlet container invokes the servlet's `init` method. After `init` completes execution, the servlet can respond to its first request. All requests are handled by a servlet's `service` method, which may be called many times during the servlet's life cycle. When the servlet container terminates the servlet, the servlet's `destroy` method is called to release servlet resources.
- The key method in every servlet is method `service`, which receives both a `ServletRequest` object and a `ServletResponse` object. These objects provide access to input and output streams that allow the servlet to read data from and send data to the client. Commonly, this method should not be overridden.
- Servlets typically extend class `HttpServlet`, which overrides method `service` to distinguish between the typical requests received from a client Web browser. The two most common HTTP request types (also known as request methods) are `get` and `post`.
- Class `HttpServlet` defines methods `doGet` and `doPost` to respond to `get` and `post` requests from a client, respectively.
- Methods `doGet` and `doPost` receive as arguments an `HttpServletRequest` object and an `HttpServletResponse` object that enable interaction between the client and the server.
- A response is sent to the client through a `PrintWriter` object returned by the `getWriter` method of the `HttpServletResponse` object.
- The `HttpServletResponse` object's `setContentType` method specifies the content type of the response to the client. This enables the client browser to understand and handle the content.
- The server `localhost` (IP address `127.0.0.1`) is a well-known host name on computers that support TCP/IP-based networking protocols such as HTTP. This host name can be used to test TCP/IP applications on the local computer.
- The Tomcat server awaits requests from clients on port 8080. This port number must be specified as part of the URL to request a servlet running in Tomcat.
- Tomcat is a fully functional implementation of the JSP and servlet standards. It includes a Web server, so it can be used as a standalone test container for JSPs and servlets.
- JSPs, servlets and their supporting files are deployed as part of Web applications. In Tomcat, Web applications are deployed in the `webapps` subdirectory of the Tomcat installation.

- A Web application has a well-known directory structure in which all the files that are part of the application reside. This directory structure can be set up by the Tomcat server administrator in the `webapps` directory, or the entire directory structure can be archived in a Web application archive file (i.e., `.war` file).
  - WAR files are typically placed in the `webapps` directory. When the Tomcat server begins execution, it extracts the contents of the WAR file into the appropriate `webapps` subdirectory structure.
- 

[Page 1276]

- The Web application directory structure is separated into a context rootthe top-level directory for an entire Web applicationand several subdirectories. The context root is the root directory for the Web application.
- All the JSPs, HTML documents, servlets and supporting files such as images and class files reside in the root directory or its subdirectories.
- The `WEB-INF` directory contains the Web application deployment descriptor (`web.xml`), which is required to deploy a Web application.
- The `WEB-INF/classes` directory contains the servlet class files and other supporting class files used in a Web application.
- The `WEB-INF/lib` directory contains Java archive (JAR) files that may include servlet class files and other supporting class files used in a Web application.
- Tomcat uses the directory names in the `webapps` subdirectory as the context names.
- HTTP `get` requests can be typed directly into your browser's `Address` or `Location` field.
- Parameters are passed as name-value pairs in a `get` request. A `?` separates the URL from the data passed as part of a `get` request. Name-value pairs are passed with the name and the value separated by `=`. Two or more name-value pairs are separated by `&`.
- Method `getParameter` of `HttpServletRequest` receives the parameter name as an argument and returns the corresponding `String` value, or `null` if the parameter is not part of the request.
- An HTTP `post` request is often used to post data from a Web-page form to a server-side form handler that processes the data. HTTP `post` requests are commonly used for passing sensitive data.
- Method `doPost` receives the same two arguments as `doGet`an object that implements interface `HttpServletRequest` to represent the client's request and an object that implements interface `HttpServletResponse` to represent the servlet's response.
- Method `sendRedirect` of `HttpServletResponse` redirects a request to the specified URL.
- When a servlet uses a relative path to reference another static or dynamic resource, the servlet assumes the same context root unless a complete URL is specified for the resource.
- Once method `sendRedirect` executes, processing of the request by the servlet that called `sendRedirect` terminates.
- When redirecting requests, the request parameters from the original request are passed as parameters to the new request. Additional request parameters can also be passed. New parameters are added to the existing request parameters. If a new parameter has the same name as an existing parameter, the new parameter value takes precedence over the original value. However, all the values are still passed.
- The complete set of values for a given request-parameter name can be obtained by calling method `getParameterValues` of `HttpServletRequest`, which receives the parameter name as an argument and returns an array of `Strings` containing the parameter values in order from the most recently to the least recently added.

- Many of today's applications are three-tier distributed applications, consisting of a user interface, business logic and database access.
  - In multitier architectures, Web servers are often used in the middle tier. Server-side components, such as servlets, execute in an application server alongside the Web server. These components provide the business logic that manipulates data from databases and communicates with client Web browsers.
  - `Servlet` method `init` takes a `ServletConfig` argument, which provides the servlet with information about its initialization parameters specified in a `servlet` element in the deployment descriptor. Each parameter appears in an `init-param` element with child elements `param-name` and `param-value`.
- 

[Page 1277]

- Web application developers can specify an ordered list of welcome files to be loaded when the request URL is not mapped to a servlet. These files are typically HTML or JSP documents.
- Welcome files are defined using the `welcome-file-list` element in the deployment descriptor.
- Element `welcome-file-list` contains one or more `welcome-file` elements. Each welcome-file element specifies the partial URL of a welcome file without a leading or trailing `/`.

## Self-Review Exercises

26.1 Fill in the blanks in each of the following statements:

- a. Classes `HttpServlet` and `GenericServlet` implement the \_\_\_\_\_ interface.
  - b. Class `HttpServlet` defines the methods \_\_\_\_\_ and \_\_\_\_\_ to respond to `get` and `post` requests from a client.
- 

[Page 1278]

- c. `HttpServletResponse` method \_\_\_\_\_ obtains a character-based output stream that enables text data to be sent to the client.
- d. The `form` attribute \_\_\_\_\_ specifies the server-side form handler , i.e., the program that handles the request.
- e. \_\_\_\_\_ is the well-known host name that refers to your own computer.

26.2 State whether each of the following is *true* or *false*. If *false*, explain why.

- a. Servlets usually are used on the client side of a networking application.
- b. Servlet methods are executed by the servlet container.
- c. The two most common HTTP requests are `get` and `put`.
- d. The well-known port number on a Web server where requests for HTML documents are made is 8080.

## Answers to Self-Review Exercises

[26.1](#) a) `Servlet`. b) `doGet`, `doPost`. c) `getWriter`. d) `action`. e) `localhost`.

[26.2](#)

- a. False. Servlets are usually used on the server side.
- b. True.
- c. False. The two most common HTTP request types are `get` and `post`. The `put` request type is often not allowed for security reasons.
- d. False. The well-known port number on a Web server where requests for HTML documents are made is 80. Port 8080 is the Tomcat servlet container's default port.

## Exercises

- 26.3 Create a servlet that displays the current date and time.
- 26.4 Create a HTML form with three input fields: first name, last name and e-mail. Use the `get` method to pass these values to a servlet. Notice how data is attached to the URL. In the servlet, verify all input fields are non-`null` and display them back to the client.
- 26.5 Create a Web application for dynamic FAQs. The application should obtain the information to create the dynamic FAQ Web page from a database that consists of a `topics` table and an `faq` table. The `topics` table has two fields: a unique integer ID for each topic (`topicID`) and a name for each topic (`topicName`). The `faq` table has three fields: the `topicID` (a foreign key), a string representing the question (`question`) and the answer to the question (`answer`). When the servlet is invoked, it should read the data from the database and return a dynamically created Web page containing each question and answer, sorted by topic. [ *Note:* The `examples` folder for this chapter contains the SQL script `faq.sql` with which you can create the `faq` database for this example. For information on executing the SQL script, please refer to [Chapter 25](#).] In the servlet's `init` method, create a `CachedRowSet` and set the database URL for the `CachedRowSet`. Sun's reference implementation of `CachedRowSet` is named `CachedRowSetImpl` and is located in the package `com.sun.rowset`.
- 26.6 Modify the Web application in [Exercise 26.5](#) so that the initial request to the servlet returns a Web page of topics in the FAQ database. Then, the user can link to another servlet that returns only the frequently asked questions for a particular topic.
- 26.7 Modify the Web application in [Fig. 26.21](#) to allow the user to see the survey results without responding to the survey.
- 26.8 Recall that the Web application in [Fig. 26.21](#) implements a Web-based survey. Write a Web application that can be used generically with any survey of the appropriate form: i.e., a question followed by a set of possible answers. Your Web application should have three servlets. The first is called to dynamically generate a list of survey names. When the user selects a survey, the second servlet should dynamically generate a `form` containing the survey options. When the user chooses an option, the third servlet should update the database and return the survey results. The `survey` database for this exercise has two tables: `surveyCategory` and `surveyResult`. Table `surveyCategory` has three fields: a unique integer ID for each survey category (`id`), a string representing the survey name (`name`) and a string representing the survey question (`question`). Table `surveyResult` has three fields: an integer ID (a foreign key) that identifies the survey category (`id`), a string representing the survey option (`surveyOption`) and an integer representing the total votes that option has received so far (`voteCount`). [ *Note:* The `examples` folder for this chapter contains the SQL script `survey.sql` with which you can create the `survey` database for this example. For information on executing the SQL script, refer to [Chapter 25](#). The sample database contains sample data for three surveys: Animals, Fruits and Sports.]

- 26.9 Write a Web application that consists of a servlet (`DirectoryServlet`) and several Web documents. Document `index.html` should be the first document the user sees. In it, you should have a series of links for other Web pages in your site. When clicked, each link should invoke the servlet with a `get` request that contains a `page` parameter. The servlet should obtain parameter `page` and redirect the request to the appropriate document.

# Chapter 27. JavaServer Pages (JSP)

*If it's a good script, I'll do it and if it's a bad script and they pay me enough, I'll do it.*

George Burns

*A fair request should be followed by the deed in silence.*

Dante Alighieri

*Talent is a question of quantity. Talent does not write one page: it writes three hundred.*

Jules Renard

*Every action must be due to one or other of seven causes: chance, nature, compulsion, habit, reasoning, anger, or appetite.*

Aristotle

## OBJECTIVES

In this chapter you will learn:

What JSPs are.

The differences between servlets and JSPs.

To create and deploy JavaServer Pages.

To use JSP's implicit objects and scriptlets to create dynamic Web pages.

To specify global JSP information with directives.

To use actions to manipulate JavaBeans in a JSP, to include resources dynamically and to forward requests to other JSPs.

[NEXT ▶](#)

## 27.1. Introduction

In [Chapter 26](#), you learned how to generate dynamic Web pages with servlets. You probably have already noticed in our examples that most of the code in our servlets generated output that consisted of the HTML elements that composed the response to the client. Only a small portion of the code dealt with the business logic. Generating responses from servlets requires that Web application developers be familiar with Java. However, many people involved in Web application development, such as Web site designers, do not know Java. It is difficult for people who are not Java programmers to implement, maintain and extend a Web application that consists of primarily of servlets. The solution to this problem is [JavaServer Pages \(JSP\)](#) an extension of servlet technology that separates the presentation from the business logic. This lets Java programmers and Web-site designers focus on their strengthswriting Java code and designing Web pages, respectively.

JavaServer Pages simplify the delivery of dynamic Web content. They enable Web application programmers to create dynamic content by reusing predefined components and by interacting with components using server-side scripting. JavaServer Page programmers can use special software components called JavaBeans and custom tag libraries that encapsulate complex, dynamic functionality. A [JavaBean](#) is a reusable component that follows certain conventions for class design that are discussed in the JavaBeans specification, which is available at [java.sun.com/products/javabeans/glasgow/index.html](http://java.sun.com/products/javabeans/glasgow/index.html). [Custom-tag libraries](#) are a powerful feature of JSP that allows Java developers to hide complex code for database access and other useful services for dynamic Web pages in [custom tags](#). Web sites use these custom tags like any other Web page element to take advantage of the more complex functionality hidden by the tag. Thus, Web-page designers who are not familiar with Java can enhance Web pages with powerful dynamic content and processing capabilities.

The classes and interfaces that are specific to JavaServer Pages programming are located in packages [javax.servlet.jsp](#) and [javax.servlet.jsp.tagext](#). We discuss many of these classes and interfaces throughout this chapter as we present JSP fundamentals. For complete JSP details, see the JavaServer Pages 2.0 specification, which can be downloaded from [java.sun.com/products/jsp/download.html](http://java.sun.com/products/jsp/download.html). We also include other JSP resources in [Section 27.10](#).

## 27.2. JavaServer Pages Overview

There are four key components to JSPs: directives, actions, scripting elements and tag libraries. **Directives** are messages to the **JSP container**—the server component that executes JSPs—that enable the programmer to specify page settings, to include content from other resources and to specify custom tag libraries for use in a **JSP**. **Actions** encapsulate functionality in predefined tags that programmers can embed in a JSP. Actions often are performed based on the information sent to the server as part of a particular client request. They also can create Java objects for use in JSP scriptlets. **Scripting elements** enable programmers to insert Java code that interacts with components in a JSP (and possibly other Web application components) to perform request processing. **Scriptlets**, one kind of scripting element, contain code fragments that describe the action to be performed in response to a user request. **Tag libraries** are part of the **tag extension mechanism** that enables programmers to create custom tags. Such tags enable Web page designers to manipulate JSP content without prior Java knowledge. These JSP component types are discussed in detail in subsequent sections.

In some ways, JavaServer Pages look like standard XHTML or XML documents. In fact, JSPs normally include XHTML or XML markup. Such markup is known as **fixed-template data** or **fixed-template text**. Fixed-template data often helps a programmer decide whether to use a servlet or a JSP. Programmers tend to use JSPs when most of the content sent to the client is fixed-template data and little or none of the content is generated dynamically with Java code. Programmers typically use servlets when only a small portion of the content sent to the client is fixed-template data. In fact, some servlets do not produce content. Rather, they perform a task on behalf of the client, then invoke other servlets or JSPs to provide a response. Note that in most cases servlet and JSP technologies are interchangeable. As with servlets, JSPs normally execute as part of a Web server.

### Software Engineering Observation 27.1

*Literal text in a JSP becomes string literals in the servlet that represents the translated JSP.*

When a JSP-enabled server receives the first request for a JSP, the JSP container translates the JSP into a Java servlet that handles the current request and future requests to the JSP. Literal text in a JSP becomes string literals in the servlet that represents the translated JSP. Any errors that occur in compiling the new servlet result in **translation-time errors**. The JSP container places the Java statements that implement the JSP's response in method `_jspService` at translation time. If the new servlet compiles properly, the JSP container invokes method `_jspService` to process the request. The JSP may respond directly or may invoke other Web application components to assist in processing the request. Any errors that occur during request processing are known as **request-time errors**.

### Performance Tip 27.1

*Some JSP containers translate JSPs to servlets at installation time. This eliminates the translation overhead for the first client that requests each JSP.*

Overall, the request-response mechanism and the JSP life cycle are the same as those of a servlet. JSPs can override methods `jspInit` and `jspDestroy` (similar to servlet methods `init` and `destroy`), which the JSP container invokes when initializing and terminating a JSP, respectively. JSP programmers can define these methods using [JSP declarations](#) part of the JSP scripting mechanism.

[◀ PREV](#)[NEXT ▶](#)

## 27.3. First JSP Example

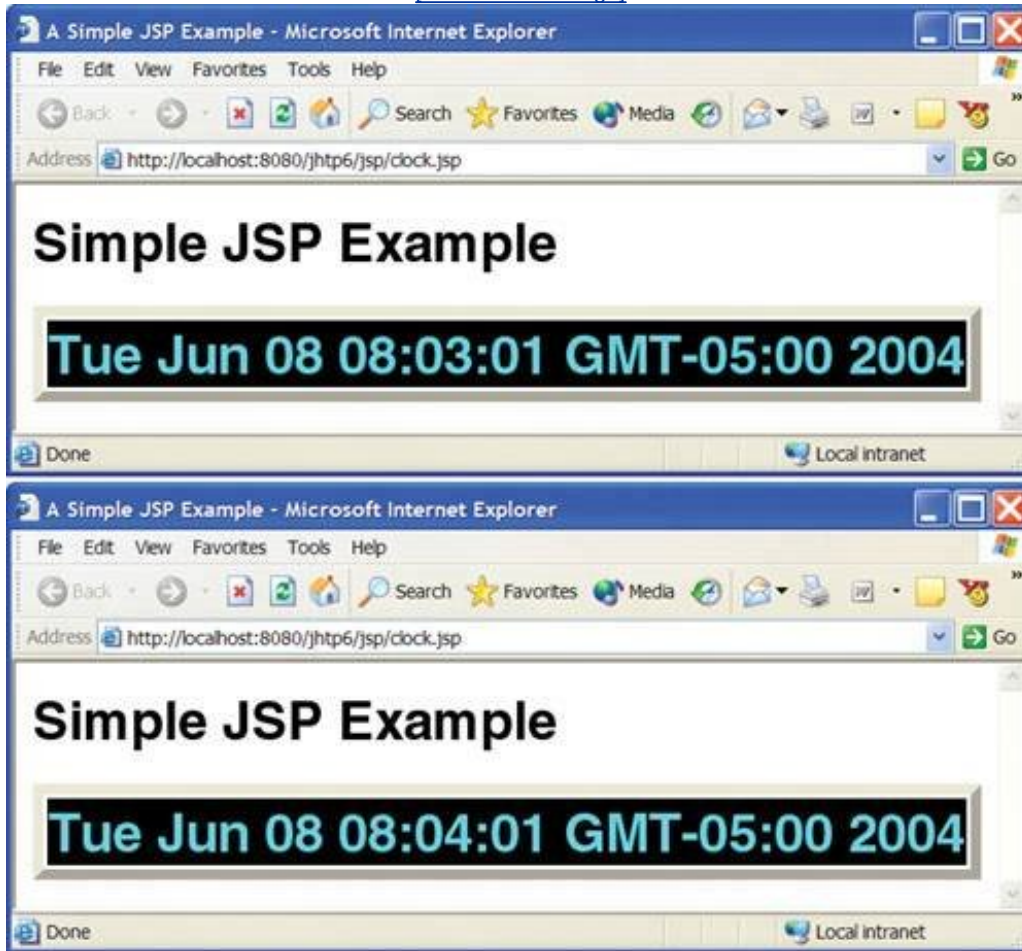

We begin our introduction to JavaServer Pages with a simple example, `clock.jsp` ([Fig. 27.1](#)), in which the current date and time are inserted into a Web page using a JSP expression.

Figure 27.1. JSP expression inserting the date and time into a Web page.

(This item is displayed on pages 1283 - 1284 in the print version)

```
1 <?xml version = "1.0"?>
2 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"
3 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">
4
5 <!-- Fig. 27.1: clock.jsp -->
6
7 <html xmlns = "http://www.w3.org/1999/xhtml">
8 <head>
9 <meta http-equiv = "refresh" content = "60" />
10 <title>A Simple JSP Example</title>
11 <style type = "text/css">
12 .big { font-family: helvetica, arial, sans-serif;
13 font-weight: bold;
14 font-size: 2em; }
15 </style>
16 </head>
17 <body>
18 <p class = "big">Simple JSP Example</p>
19 <table style = "border: 6px outset;">
20 <tr>
21 <td style = "background-color: black;">
22 <p class = "big" style = "color: cyan;">
23 <!-- JSP expression to insert date/time -->
24 <%= new java.util.Date() %>
25 </p>
26 </td>
27 </tr>
28 </table>
29 </body>
30 </html>
```

[\[View full size image\]](#)

[Page 1284]

As you can see, most of `clock.jsp` consists of XHTML markup. [Note: We assume that the reader already knows XHTML and Cascading Style Sheets (CSS). For those who are not familiar with XHTML and CSS, we have included three chapters from our book *Internet & World Wide Web How to Program, Third Edition* as PDF documents on the CD that accompanies this book: Introduction to XHTML: Part 1, Introduction to XHTML: Part 2 and Cascading Style Sheets (CSS).] In cases like this, JSPs are easier to implement than servlets. In a servlet that performs the same task as this JSP, each line of XHTML markup typically is a separate Java statement that outputs the string representing the markup as part of the response to the client. Writing code to output markup can often lead to errors. Most JSP editors provide syntax coloring to help programmers check that their markup follows proper syntax.

## Software Engineering Observation 27.2

*JavaServer Pages are easier to implement than servlets when the response to a client request consists primarily of markup that remains constant between requests.*

[Page 1285]

The JSP in [Fig. 27.1](#) generates an XHTML document that displays the current date and time. The key line in this JSP (line 24) is the expression

```
<%= new java.util.Date() %>
```

JSP expressions are delimited by `<%=` and `%>`. The preceding expression creates a new instance of class `Date` (package `java.util`). By default, a `Date` object is initialized with the current date and time. When the client requests this JSP, the preceding expression inserts the `String` representation of the date and time in the response to the client. [*Note:* Because the client of a JSP could be anywhere in the world, the JSP should return the date in the client locale's format. However, the JSP executes on the server, so the server's locale determines the `String` representation of the `Date`. In [Fig. 27.10](#), `clock2.jsp` determines the client's locale, then uses a `DateFormat` (package `java.text`) object to format the date using that locale.]

## Software Engineering Observation 27.3

*The JSP container converts the result of every JSP expression into a string that is output as part of the response to the client.*

We use the XHTML [meta element](#) in line 9 to set a [refresh interval](#) of 60 seconds for the document. This causes the browser to request `clock.jsp` every 60 seconds. For each request to `clock.jsp`, the JSP container reevaluates the expression in line 24, creating a new `Date` object with the server's current date and time.

As in [Chapter 26](#), we use Apache Tomcat to test our JSPs in the `jhttp6` Web application we created previously. For details on creating and configuring the `jhttp6` Web application, review [Section 26.3](#) and [Section 26.4.1](#). To test `clock.jsp`, create a new directory called `jsp` in the `jhttp6` subdirectory of Tomcat's `webapps` directory. Next, copy `clock.jsp` into the `jsp` directory. Open your Web browser and enter the following URL to test `clock.jsp`:

```
http://localhost:8080/jhttp6/jsp/clock.jsp
```

When you first invoke the JSP, you may notice a brief delay as Tomcat translates the JSP into a servlet and invokes the servlet to respond to your request. [*Note:* It is not necessary to create a directory named `jsp` in a Web application. We use this directory to separate the examples in this chapter from the servlet examples in [Chapter 26](#).]

## 27.4. Implicit Objects

Implicit objects provide access to many servlet capabilities in the context of a JavaServer Page. Implicit objects have four scopes: application, page, request and session. The JSP container owns objects with **application scope**. Any JSP can manipulate such objects. Objects with **page scope** exist only in the page that defines them. Each page has its own instances of the page-scope implicit objects. Objects with **request scope** exist for the duration of the request. For example, a JSP can partially process a request, then forward it to a servlet or another JSP for further processing. Request-scope objects go out of scope when request processing completes with a response to the client. Objects with **session scope** exist for the client's entire browsing session. [Figure 27.2](#) describes the JSP implicit objects and their scopes. This chapter demonstrates several of these objects.

Figure 27.2. JSP implicit objects.

(This item is displayed on page 1286 in the print version)

Implicit object	Description
<i>Application Scope</i>	
<code>application</code>	A <code>javax.servlet.ServletContext</code> object that represents the container in which the JSP executes.
<i>Page Scope</i>	
<code>config</code>	A <code>javax.servlet.ServletConfig</code> object that represents the JSP configuration options. As with servlets, configuration options can be specified in a Web application descriptor.
<code>exception</code>	A <code>java.lang.Throwable</code> object that represents an exception that is passed to a JSP error page. This object is available only in a JSP error page.
<code>out</code>	A <code>javax.servlet.jsp.JspWriter</code> object that writes text as part of the response to a request. This object is used implicitly with JSP expressions and actions that insert string content in a response.
<code>page</code>	An <code>Object</code> that represents the <code>this</code> reference for the current JSP instance.
<code>pageContext</code>	A <code>javax.servlet.jsp.PageContext</code> object that provides JSP programmers with access to the implicit objects discussed in this table.
<code>response</code>	An object that represents the response to the client and is normally an instance of a class that implements <code>HttpServletResponse</code> (package <code>javax.servlet.http</code> ). If a protocol other than HTTP is used, this object is an instance of a class that implements <code>ServletResponse</code> .
<i>Request Scope</i>	
<code>request</code>	An object that represents the client request and is normally an instance of a class that implements <code>HttpServletRequest</code> (package <code>javax.servlet.http</code> ). If a protocol other than HTTP is used, this object is an instance of a subclass of <code>ServletRequest</code> .
<i>Session Scope</i>	

Implicit object	Description
<code>session</code>	A <code>javax.servlet.http.HttpSession</code> object that represents the client session information if such a session has been created. This object is available only in pages that participate in a session.

Note that many of the implicit objects extend classes or implement interfaces discussed in [Chapter 26](#). Thus, JSPs can use the same methods that servlets use to interact with such objects, as described in [Chapter 26](#). Most of the examples in this chapter use one or more of the implicit objects in [Fig. 27.2](#).

## 27.5. Scripting

JavaServer Pages often present dynamically generated content as part of an XHTML document that is sent to the client in response to a request. In some cases, the content is static but is output only if certain conditions are met during a request (e.g., providing values in a `form` that submits a request). JSP programmers can insert Java code and logic in a JSP using scripting.

### 27.5.1. Scripting Components

The JSP scripting components include scriptlets, comments, expressions, declarations and escape sequences. This section describes each of these scripting components. Many of these are demonstrated in [Fig. 27.4](#) at the end of [Section 27.5.2](#).

Scriptlets are blocks of code delimited by `<% and %>`. They contain Java statements that the container places in method `_jspService` at translation time.

JSPs support three comment styles: JSP comments, XHTML comments and scripting-language comments. **JSP comments** are delimited by `<!-- and -->`. These can be placed throughout a JSP, but not inside scriptlets. **XHTML comments** are delimited with `<!-- and -->`. These, too, can be placed throughout a JSP, but not inside scriptlets. Scripting language comments are currently Java comments, because Java currently is the only JSP scripting language. Scriptlets can use Java's end-of-line `//` comments and traditional comments (delimited by `/* and */`). JSP comments and scripting-language comments are ignored and do not appear in the response to a client. When clients view the source code of a JSP response, they will see only the XHTML comments in the source code. The different comment styles are useful for separating comments that the user should be able to see from those that document logic processed on the server.

#### Common Programming Error 27.1

*Placing a JSP comment or XHTML comment inside a scriptlet is a translation-time syntax error that prevents the JSP from being translated properly.*

As we discussed in [Section 27.3](#), JSP expressions are delimited by `<%= and %>` and contain a Java expression that is evaluated when a client requests the JSP containing the expression. The container converts the result of a JSP expression to a `String` object, then outputs the `String` as part of the response to the client.

Declarations, delimited by `<%! and %>`, enable a JSP programmer to define variables and methods for use in a JSP. Variables become instance variables of the servlet class that represents the translated JSP. Similarly, methods become members of the class that represents the translated JSP. Declarations of variables and methods in a JSP use Java syntax. Thus, a variable declaration must end with a semicolon, as in

```
<%! int counter = 0; %>
```

## Software Engineering Observation 27.4

JSPs should not store client state information in instance variables. Rather, they should use the JSP implicit `session` object. For more information on how to use the `session` object, visit Sun's J2EE tutorial at [java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html](http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html).

Special characters or character sequences that the JSP container normally uses to delimit JSP code can be included in a JSP as literal characters in scripting elements, fixed template data and attribute values using [escape sequences](#). [Figure 27.3](#) shows the literal character or characters and the corresponding escape sequences and discusses where to use the escape sequences.

Figure 27.3. JSP escape sequences.

(This item is displayed on page 1288 in the print version)

Literal	Escape sequence	Description
<code>&lt;%</code>	<code>&lt;\%</code>	The character sequence <code>&lt;%</code> normally indicates the beginning of a scriptlet. The <code>&lt;\%</code> escape sequence places the literal characters <code>&lt;%</code> in the response to the client.
<code>%&gt;</code>	<code>%\&gt;</code>	The character sequence <code>%&gt;</code> normally indicates the end of a scriptlet. The <code>%\&gt;</code> escape sequence places the literal characters <code>%&gt;</code> in the response to the client.
<code>'</code> <code>"</code> <code>\</code>	<code>\'</code> <code>\"</code> <code>\\</code>	As with string literals in a Java program, the escape sequences for characters <code>'</code> , <code>"</code> and <code>\</code> allow these characters to appear in attribute values. Remember that the literal text in a JSP becomes string literals in the servlet that represents the translated JSP.

[Page 1288]

### 27.5.2. Scripting Example

[Figure 27.4](#) demonstrates responding to `get` requests with basic scripting capabilities. The JSP enables the user to input a first name, then outputs that name in the response. Using scripting, the JSP determines whether a `firstName` parameter was passed as part of the request. If not, the JSP returns an XHTML document containing a `form` through which the user can input a first name. Otherwise, the JSP obtains the `firstName` value and uses it as part of an XHTML document that welcomes the user to JavaServer Pages.

Figure 27.4. Scripting a JavaServer Page `welcome.jsp`.

(This item is displayed on pages 1289 - 1290 in the print version)

```
1 <?xml version = "1.0" ?>
```

```
2 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"
3 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">
4
5 <!-- Fig. 27.4: welcome.jsp -->
6 <!-- JSP that processes a "get" request containing data. -->
7
8 <html xmlns = "http://www.w3.org/1999/xhtml">
9
10 <!-- head section of document -->
11 <head>
12 <title>Processing "get" requests with data</title>
13 </head>
14
15 <!-- body section of document -->
16 <body>
17 <% // begin scriptlet
18
19 String name = request.getParameter("firstName");
20
21 if (name != null)
22 {
23 %> <!-- end scriptlet to insert fixed template data --%>
24
25 <h1>
26 Hello <%= name %>,

27 Welcome to JavaServer Pages!
28 </h1>
29
30 <% // continue scriptlet
31
32 } // end if
33 else {
34
35 %> <!-- end scriptlet to insert fixed template data --%>
36
37 <form action = "welcome.jsp" method = "get">
38 <p>Type your first name and press Submit</p>
39
40 <p><input type = "text" name = "firstName" />
41 <input type = "submit" value = "Submit" />
42 </p>
43 </form>
44
45 <% // continue scriptlet
46
47 } // end else
48
49 %> <!-- end scriptlet --%>
50 </body>
51
52 </html> <!-- end XHTML document -->
```

[\[View full size image\]](#)

Note that most of the code in [Fig. 27.4](#) is XHTML markup (i.e., fixed-template data). Throughout the `body` element (lines 1650) are several scriptlets (lines 1723, 3035 and 4549) and a JSP expression (line 26). Note that three JSP comment styles appear in this JSP (at line 5, line 17 and line 23).

The scriptlets define an `if...else` statement that determines whether the JSP received a value for the first name as part of the request. Line 19 uses method `getParameter` of JSP implicit object `request` (an `HttpServletRequest` object) to obtain the value for parameter `firstName` and assigns the result to variable `name`. Line 21 determines whether or not `name` is `null`. If it is not `null`, a value for the first name was passed to the JSP as part of the request. If this condition is `true`, the scriptlet terminates temporarily so that the fixedtemplate data at lines 2528 can be output. The JSP expression in line 26 outputs the value of variable `name` (i.e., the first name passed to the JSP as a request parameter). The scriptlet continues at lines 3035 with the closing brace of the `if` statement's body and the beginning of the `else` part of the `if...else` statement. If the condition at line 21 is `false`, lines 2528 are not output. Instead, lines 3743 output a `form` element. The user can type a first name in the `form` and press the Submit button to request the JSP again and execute the `if` statement's body (lines 2528).

## Software Engineering Observation 27.5

*Scriptlets, expressions and fixed-template data can be intermixed in a JSP to create different responses based on the information in a request.*

## Error-Prevention Tip 27.1

*It is sometimes difficult to debug errors in a JSP, because the line numbers reported by a JSP container normally refer to the servlet that represents the translated JSP, not the original JSP line numbers. Program development environments enable JSPs to be compiled in the environment, so you can see syntax error messages. These messages include the statement in the servlet that represents the translated JSP, which can be helpful in determining the error.*

## Error-Prevention Tip 27.2

*Many JSP containers store the source code for the servlets that represent the translated JSPs. For example, the Tomcat installation directory contains a subdirectory called `work` in which you can find the source code for the servlets translated by Tomcat. Recall from [Chapter 26](#) that the log files located in the `logs` subdirectory of the Tomcat installation directory are also helpful for determining the errors.*

## Error-Prevention Tip 27.3

*Always put the closing brace for the `if` statement and the `else` statement in the same scriptlet.*

To test [Fig. 27.4](#) in Tomcat, copy `welcome.jsp` into the `jsp` directory created in [Section 27.3](#). Then, open your Web browser and enter the following URL:

```
http://localhost:8080/jhttp6/jsp/welcome.jsp
```

---

[Page 1291]

When you first execute the JSP, it displays the `form` in which you can enter your first name, because the preceding URL does not pass a `firstName` parameter to the JSP. After you submit your first name, your browser should appear as shown in the second screen capture of [Fig. 27.4](#). [*Note:* As with servlets, it is possible to pass get request arguments as part of the URL. The following URL supplies the `firstName` parameter to `welcome.jsp`.]

```
http://localhost:8080/jhttp6/jsp/welcome.jsp?firstName=Paul
```

## 27.6. Standard Actions

We continue our JSP discussion with the [JSP standard actions \(Fig. 27.5\)](#). These actions provide JSP implementors with access to several of the most common tasks performed in a JSP, such as including content from other resources, forwarding requests to other resources and interacting with JavaBean software components. JSP containers process actions at request time. Actions are delimited by `<jsp:action>` and `</jsp:action>`, where *action* is the standard action name. In cases where nothing appears between the starting and ending tags, the XML empty element syntax `<jsp:action />` can be used. [Figure 27.5](#) summarizes the JSP standard actions, which we use in the next several subsections.

Figure 27.5. JSP standard actions.

Action	Description
<code>&lt;jsp:include&gt;</code>	Dynamically includes another resource in a JSP. As the JSP executes, the referenced resource is included and processed.
<code>&lt;jsp:forward&gt;</code>	Forwards request processing to another JSP, servlet or static page. This action terminates the current JSP's execution.
<code>&lt;jsp:plugin&gt;</code>	Allows a plug-in component to be added to a page in the form of a browser-specific <code>object</code> or <code>embed</code> HTML element. In the case of a Java applet, this action enables the browser to download and install the Java Plug-in, if it is not already installed on the client computer.
<code>&lt;jsp:param&gt;</code>	Used with the <code>include</code> , <code>forward</code> and <code>plugin</code> actions to specify additional name-value pairs of information for use by these actions.
<i>JavaBean Manipulation</i>	
<code>&lt;jsp:useBean&gt;</code>	Specifies that the JSP uses a JavaBean instance (i.e., an object of the class that declares the JavaBean). This action specifies the scope of the object and assigns it an ID (i.e., a variable name) that scripting components can use to manipulate the bean.
<code>&lt;jsp:setProperty&gt;</code>	Sets a property in the specified JavaBean instance. A special feature of this action is automatic matching of request parameters to bean properties of the same name.
<code>&lt;jsp:getProperty&gt;</code>	Gets a property in the specified JavaBean instance and converts the result to a string for output in the response.

### 27.6.1. `<jsp:include>` Action

JavaServer Pages support two include mechanisms: the `<jsp:include>` action and the `include` directive. Action `<jsp:include>` enables dynamic content to be included in a JavaServer Page at request time. If the included resource changes between requests, the next request to the JSP containing the `<jsp:include>` action includes the resource's new content. On the other hand, the `include` directive copies the content into the JSP once, at JSP translation time. If the included resource changes, the new content will not be reflected

in the JSP that used the `include` directive, unless that JSP is recompiled, which normally would occur only if a new version of the JSP is installed. [Figure 27.6](#) describes the attributes of action `<jsp:include>`.

Figure 27.6. Action `<jsp:include>` attributes.

Attribute	Description
<code>page</code>	Specifies the relative URI path of the resource to include. The resource must be part of the same Web application.
<code>flush</code>	Specifies whether the implicit object <code>out</code> should be flushed before the <code>include</code> is performed. If <code>true</code> , the <code>JspWriter out</code> is flushed prior to the inclusion, hence you could no longer forward to another page later on. The default value is <code>false</code> .

### Software Engineering Observation 27.6

*According to the JavaServer Pages 2.0 specification, a JSP container is allowed to determine whether a resource included with the `include` directive has changed. If so, the container can recompile the JSP that included the resource. However, the specification does not provide a mechanism to indicate a change in an included resource to the container.*

### Performance Tip 27.2

*The `<jsp:include>` action is more flexible than the `include` directive, but requires more over-head when page contents change frequently. Use the `<jsp:include>` action only when dynamic content is necessary.*

### Common Programming Error 27.2

*Specifying in a `<jsp:include>` action a page that is not part of the same Web application is a request-time errorthe `<jsp:include>` action will not include any content.*

The next example demonstrates action `<jsp:include>` using four XHTML and JSP resources that represent both static and dynamic content. JavaServer Page `include.jsp` ([Fig. 27.7](#)) includes three other resources: `banner.html` ([Fig. 27.8](#)), `toc.html` ([Fig. 27.9](#)) and `clock2.jsp` ([Fig. 27.10](#)). JavaServer Page `include.jsp` creates an XHTML document containing a `table` in which `banner.html` spans two columns across the top of the `table`, `toc.html` is the left column of the second row and `clock2.jsp` is the right column of the second

```

Figure 27.10. JSP `clock2.jsp` to include as the main content in the XHTML document created by [Fig. 27.7](#).

(This item is displayed on page 1296 in the print version)

```
1 <!-- Fig. 27.10: clock2.jsp -->
2 <!-- date and time to include in another document -->
3
4 <table>
5 <tr>
6 <td style = "background-color: black;">
7 <p class = "big" style = "color: cyan; font-size: 3em;
8 font-weight: bold;">
9
10 <%-- script to determine client local and --%>
11 <%-- format date accordingly --%>
12 <%
13 // get client locale
14 java.util.Locale locale = request.getLocale();
15
16 // get DateFormat for client's Locale
17 java.text.DateFormat dateFormat =
18 java.text.DateFormat.getDateTimeInstance(
19 java.text.DateFormat. LONG,
20 java.text.DateFormat. LONG, locale);
21
22 %> <%-- end script --%>
23
24 <%-- output date --%>
25 <%= dateFormat.format(new java.util.Date()) %>
26 </p>
27 </td>
28 </tr>
29 </table>
```

[Figure 27.10](#) (`clock2.jsp`) demonstrates how to determine the client's **Locale** (package `java.util`) and uses that **Locale** to format a **Date** with a **DateFormat** (package `java.text`) object. Line 14 invokes the `request` object's `getLocale` method, which returns the client's **Locale**. Lines 17-20 invoke `DateFormat` static method `getDateTimeInstance` to obtain a `DateFormat` object. The first two arguments indicate that the date and time formats should each be `LONG` format (other options are `FULL`, `MEDIUM`, `SHORT` and `DEFAULT`, see [java.sun.com/j2se/5.0/docs/api/java/text/DateFormat.html](http://java.sun.com/j2se/5.0/docs/api/java/text/DateFormat.html) for details of these formats). The third argument specifies the **Locale** for which the `DateFormat` object should format the date. Line 25 invokes the `DateFormat` object's `format` method to produce a **String** representation of the **Date**. The `DateFormat` object formats this **String** for the **Locale** specified in line 20. [*Note:* This example works for Western languages that use the ISO-8859-1 character set. For other languages, the JSP must specify the proper character set using the JSP `page` directive ([Section 27.7.1](#)). At the site [java.sun.com/j2se/5.0/docs/guide/intl/encoding.doc.html](http://java.sun.com/j2se/5.0/docs/guide/intl/encoding.doc.html), Sun provides a list of character encodings. The response's content type defines the character set to use in the response. The content type has the form "*contentType*; charset= *encoding*" (e.g., "`text/html; charset=ISO-8859-1`".)]

To test [Fig. 27.7](#) in Tomcat, copy `banner.html`, `toc.html`, `clock2.jsp`, `include.jsp` and the `images` directory into the `jsp` directory created in [Section 27.3](#). Open your Web browser and enter the following URL:

```
http://localhost:8080/jhttp6/jsp/include.jsp
```

## 27.6.2. `<jsp:forward>` Action

Action `<jsp:forward>` enables a JSP to forward request processing to a different resource, such as an error page. Request processing by the original JSP terminates as soon as the JSP forwards the request. Action `<jsp:forward>` has only a page attribute that specifies the relative URL of the resource (in the same Web application) to which the request should be forwarded.

### Software Engineering Observation 27.7

*When using the `<jsp:forward>` action, the resource to which the request will be forwarded must be in the same context (Web application) as the JSP that originally received the request.*

JavaServer Page `forward1.jsp` ([Fig. 27.11](#)) is a modified version of `welcome.jsp` ([Fig. 27.4](#)). The primary difference is in lines 2023, in which JavaServer Page `forward1.jsp` forwards the request to JavaServer Page `forward2.jsp` ([Fig. 27.12](#)). Note the `<jsp:param>` action in lines 2122. This action adds a request parameter representing the date and time at which the initial request was received to the request object that is forwarded to `forward2.jsp`.

Figure 27.11. JSP `forward1.jsp` receives a `firstName` parameter, adds a date to the request parameters and forwards the request to `forward2.jsp` for further processing.

(This item is displayed on pages 1297 - 1298 in the print version)

```

1 <?xml version = "1.0" ?>

31 </tr>
32 </table>
33 </body>
34 </html>

```

[\[View full size image\]](#)

The `<jsp:param>` action specifies name-value pairs of information that are passed to the `<jsp:include>`, `<jsp:forward>` and `<jsp:plugin>` actions. Every `<jsp:param>` action has two required attributes `name` and `value`. If a `<jsp:param>` action specifies a parameter that already exists in the request, the new value for the parameter takes precedence over the original one. All the values for that parameter can be obtained by using the JSP implicit object `request`'s `getParameterValues` method, which returns an array of `Strings`.

JSP `forward2.jsp` uses the `name` specified in the `<jsp:param>` action ("`date`") to obtain the date and time. It also uses the `firstName` parameter originally passed to `forward1.jsp` to obtain the user's first name. The JSP expressions in [Fig. 27.12](#) (lines 21 and 28) insert the request parameter values in the response to the client. The screen capture in [Fig. 27.11](#) shows the initial interaction with the client. The screen capture in [Fig. 27.12](#) shows the results returned to the client after the request was forwarded to `forward2.jsp`.

To test [Fig. 27.11](#) and [Fig. 27.12](#) in Tomcat, copy `forward1.jsp` and `forward2.jsp` into the `jsp` directory created in [Section 27.3](#). Open your Web browser and enter the following URL to test `forward1.jsp`:

```
http://localhost:8080/jhttp6/jsp/forward1.jsp
```

### 27.6.3. `<jsp:useBean>` Action

Action `<jsp:useBean>` enables a JSP to manipulate a Java object. This action creates a Java object or locates an existing object for use in the JSP. [Figure 27.13](#) summarizes action `<jsp:useBean>`'s attributes. If attributes `class` and `beanName` are not specified, the JSP container attempts to locate an existing object of the type specified in attribute `type`. Like JSP implicit objects, objects specified with action `<jsp:useBean>` have a scope `page`, `request`, `session` or `application` that indicates where they can be used in a Web application. Objects with `page` scope are accessible only by the `page` in which they are defined. Multiple JSP pages can potentially access objects in other scopes. For example, all JSPs that process a single request can access an object in `request` scope.

Figure 27.13. Attributes of the `<jsp:useBean>` action.

Attribute	Description
<code>id</code>	The name used to manipulate the Java object with actions <code>&lt;jsp:setProperty&gt;</code> and <code>&lt;jsp:getProperty&gt;</code> . A variable of this name is also declared for use in JSP scripting elements. The name specified here is case sensitive.
<code>scope</code>	The scope in which the Java object is accessible <code>page</code> , <code>request</code> , <code>session</code> or <code>application</code> . The default scope is <code>page</code> .
<code>class</code>	The fully qualified class name of the Java object.
<code>beanName</code>	The name of a JavaBean that can be used with method <code>instantiate</code> of class <code>java.beans.Beans</code> to load a JavaBean into memory.

Attribute	Description
<code>type</code>	The type of the JavaBean. This can be the same type as the <code>class</code> attribute, a superclass of that type or an interface implemented by that type. The default value is the same as for attribute <code>class</code> . A <code>ClassCastException</code> occurs if the Java object is not of the type specified with attribute <code>type</code> .

### Common Programming Error 27.3

*One or both of the `<jsp:useBean>` attributes `class` and `type` must be specified otherwise, a translation-time error occurs.*

Many Web sites place rotating advertisements on their Web pages. Each visit to one of these pages typically results in a different advertisement being displayed in the user's Web browser. Typically, clicking an advertisement takes you to the Web site of the company that placed the advertisement. Our first example of `<jsp:useBean>` demonstrates a simple advertisement rotator bean that cycles through a list of five advertisements. In this example, the advertisements are covers for some of our books. Clicking a cover takes you to the Amazon.com Web site, where you can read about and possibly order the book.

[Page 1301]

The `Rotator` bean (Fig. 27.14) has three methods: `getImage`, `getLink` and `nextAd`. Method `getImage` returns the image file name for the book-cover image. Method `getLink` returns the hyperlink to the book at Amazon.com. Method `nextAd` updates the `Rotator` so that the next calls to `getImage` and `getLink` will return information for a different advertisement. Methods `getImage` and `getLink` each represent a read-only JavaBean property `image` and `link`, respectively. These are read-only properties because no `set` methods are provided to change their values. `Rotator` keeps track of the current advertisement with its `selectedIndex` variable, which is updated by invoking method `nextAd`.

[Page 1302]

Figure 27.14. `Rotator` bean that maintains a set of advertisements.

(This item is displayed on page 1301 in the print version)

```

1 // Fig. 27.14: Rotator.java
2 // A JavaBean that rotates advertisements.
3 package com.deitel.jhttp6.jsp.beans;
4
5 public class Rotator
6 {
7 private String images[] = { "images/advjHTP1.jpg",
8 "images/cppHTP4.jpg", "images/iw3HTP2.jpg",
9 "images/jwsFEP1.jpg", "images/vbnetHTP2.jpg" };
10
11 private String links[] = {
12 "http://www.amazon.com/exec/obidos/ASIN/0130895601/" +
13 "deitelassociatin",
14 "http://www.amazon.com/exec/obidos/ASIN/0130384747/" +
15 "deitelassociatin",
16 "http://www.amazon.com/exec/obidos/ASIN/0130308978/" +
17 "deitelassociatin",
18 "http://www.amazon.com/exec/obidos/ASIN/0130461342/" +
19 "deitelassociatin",
20 "http://www.amazon.com/exec/obidos/ASIN/0130293636/" +
21 "deitelassociatin" };
22
23 private int selectedIndex = 0;
24
25 // returns image file name for current ad
26 public String getImage()
27 {
28 return images[selectedIndex];
29 } // end method getImage
30
31 // returns the URL for ad's corresponding Web site
32 public String getLink()
33 {
34 return links[selectedIndex];
35 } // end method getLink
36
37 // update selectedIndex so next calls to getImage and
38 // getLink return a different advertisement
39 public void nextAd()
40 {
41 selectedIndex = (selectedIndex + 1) % images.length;
42 } // end method nextAd
43 } // end class Rotator

```

JavaBeans were originally intended to be manipulated visually in [visual development environments](#) (often called [builder tools](#) or IDEs). Builder tools that support beans provide programmers with tremendous flexibility by allowing them to reuse and integrate existing disparate components that, in many cases, were never intended to be used together. These components can be linked together to create applets, applications or even new beans for reuse by others.

When used in an IDE, JavaBeans usually adhere to the following coding conventions:

1. implement the `Serializable` interface
2. provide a `public` no-argument constructor

3. provide *get* and/or *set* methods for properties (which are normally implemented as fields).

When used on the server side, such as within a JSP or a servlet, JavaBeans are less restricted. For example, the `Rotator` bean does not implement the `Serializable` interface because there is no need to save and load the `Rotator` bean as a file. Recall that by default, if the programmer does not explicitly add constructors to a class, a `public` no-argument constructor is generated automatically. Also note that in the `Rotator` bean, properties `image` and `link` are read only because they provide only *get* methods.

Lines 78 of JavaServer Page `adrotator.jsp` (Fig. 27.15) obtain a reference to an instance of class `Rotator`. The `id` for the bean is `rotator`. The JSP uses this name to manipulate the bean. The scope of the object is `session`, so that every client will see the same sequence of ads during their browsing sessions. When `adrotator.jsp` receives a request from a new client, the JSP container creates the bean and stores it in that client's `session` (an `HttpSession` object). In each request to this JSP, line 19 uses the `rotator` reference created in line 7 to invoke the `Rotator` bean's `nextAd` method. Thus, each request will receive the next advertisement selected by the `Rotator` bean. Lines 2429 define a hyperlink to the Amazon.com site for a particular book. Lines 2425 introduce action `<jsp:getProperty>` to obtain the value of the `Rotator` bean's `link` property. Action `<jsp:getProperty>` has two attributes `name` and `property` that specify the bean object to manipulate and the property to get. If the JavaBean object uses standard JavaBean naming conventions, the method used to obtain the `link` property value from the bean should be `getLink`. Action `<jsp:getProperty>` invokes `getLink` on the bean referenced with `rotator`, converts the return value into a `String` and outputs the `String` as part of the response to the client. The `link` property becomes the value of the hyperlink's `href` attribute. The hyperlink is represented in the resulting Web page as the book cover image. Lines 2728 create an `img` element and use another `<jsp:getProperty>` action to obtain the `Rotator` bean's `image` property value.

---

[Page 1303]

---

[Page 1304]

Figure 27.15. JSP `adrotator.jsp` uses a `Rotator` bean to display a different advertisement on each request for the page.

(This item is displayed on pages 1302 - 1303 in the print version)

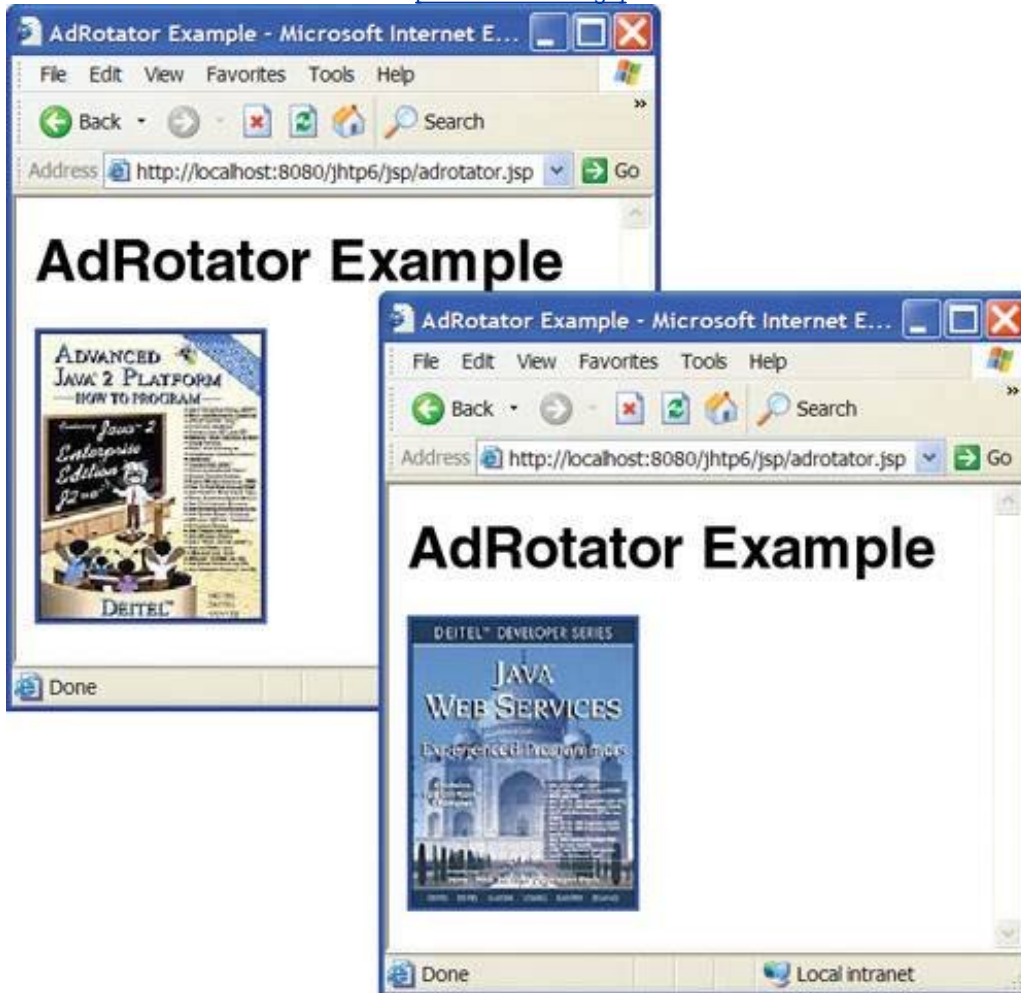

```
1 <?xml version = "1.0"?>
2 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"
3 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">
4
5 <!-- Fig. 27.15: adrotator.jsp -->
6
7 <jsp:useBean id = "rotator" scope = "session"
8 class = "com.deitel.jhttp6.jsp.beans.Rotator" />
9
10 <html xmlns = "http://www.w3.org/1999/xhtml">
11 <head>
12 <title>AdRotator Example</title>
13 <style type = "text/css">
14 .big { font-family: helvetica, arial, sans-serif;
15 font-weight: bold;
16 font-size: 2em }
17 </style>
18 <!-- update advertisement --%>
19 <% rotator.nextAd(); %>
20 </head>
21 <body>
22 <p class = "big">AdRotator Example</p>
23 <p>
24 <a href = "<jsp:getProperty name = "rotator"
```

```

25 property = "link" />">
26
27 <img src = "<jsp:getProperty name = "rotator"
28 property = "image" />" alt = "advertisement" />
29
30 </p>
31 </body>
32 </html>

```

[\[View full size image\]](#)

The link and image properties can also be obtained with JSP expressions. For example, action `<jsp:getProperty>` in lines 2425 can be replaced with the expression

```
<%= rotator.getLink() %>
```

Similarly, action `<jsp:getProperty>` in lines 2728 can be replaced with the expression

```
<%= rotator.getImage() %>
```

The benefit of using actions is that someone who is unfamiliar with Java can be told the name of a property and the name of a bean, and it is the action's responsibility to invoke the appropriate methods. The Java programmer's job is to create a bean that supports the capabilities required by the page designer.

To test `adrotator.jsp` in Tomcat, copy `adrotator.jsp` into the `jsp` directory created in [Section 27.3](#). You should have copied the `images` directory into the `jsp` directory when you tested [Fig. 27.7](#). If not, you must copy the `images` directory there now. Copy `Rotator.class` into the `jhttp6` Web application's `WEBINF\classes\com\deitel\jhttp6\jsp\beans` directory in Tomcat. [*Note:* This example will work only if the proper package directory structure for `Rotator` is defined in the `classes` directory. `Rotator` is declared in package `com.deitel.jhttp6.jsp.beans`.] Open your Web browser and enter the following URL to test `adrotator.jsp`:

```
http://localhost:8080/jhttp6/jsp/adrotator.jsp
```

Try reloading this JSP several times in your browser to see the advertisement change with each request.

Action `<jsp:setProperty>` sets JavaBean property values and is particularly useful for mapping request parameter values to JavaBean properties. Request parameters can be used to set properties of primitive types `boolean`, `byte`, `char`, `short`, `int`, `long`, `float` and `double` and `java.lang` types `String`, `Boolean`, `Byte`, `Character`, `Short`, `Integer`, `Long`, `Float` and `Double`. [Figure 27.16](#) summarizes the `<jsp:setProperty>` attributes.

Figure 27.16. Attributes of the `<jsp:setProperty>` action.

(This item is displayed on page 1305 in the print version)

Attribute	Description
<code>name</code>	The ID of the JavaBean for which a property (or properties) will be set.
<code>property</code>	The name of the property to set. Specifying <code>"*"</code> for this attribute specifies that the JSP should match the request parameters to the properties of the bean. For each request parameter that matches (i.e., the name of the request parameter is identical to the bean's property name), the corresponding property in the bean is set to the value of the parameter. If the value of the request parameter is <code>" "</code> , the property value in the bean remains unchanged.
<code>param</code>	If request parameter names do not match bean property names, this attribute can be used to specify which request parameter should be used to obtain the value for a specific bean property. This attribute is optional. If this attribute is omitted, the request parameter names must match the bean property names.
<code>value</code>	The value to assign to a bean property. The value typically is the result of a JSP expression. This attribute is particularly useful for setting bean properties that cannot be set using request parameters. This attribute is optional. If this attribute is omitted, the JavaBean property must be of a type that can be set using request parameters.

Software Engineering Observation 27.8

Action `<jsp:setProperty>` can use request-parameter values to set JavaBean properties of the following types: *Strings*, *primitive types* (`boolean`, `byte`, `char`, `short`, `int`, `long`, `float` and `double`) and *type-wrapper classes* (`Boolean`, `Byte`, `Character`, `Short`, `Integer`, `Long`, `Float` and `Double`). See [Fig. 27.22](#) for an example.

## Common Programming Error 27.4

*Conversion errors occur if you use action `<jsp:setProperty>`'s `value` attribute to set *JavaBean* property types that cannot be set with request parameters.*

## 27.7. Directives

**Directives** are messages to the JSP container that enable the programmer to specify page settings (e.g., the error page to invoke if an error occurs), to include content from other resources and to specify custom-tag libraries for use in a JSP. Directives (delimited by `<%@` and `%>`) are processed at translation time. Thus, directives do not produce any immediate output, because they are processed before the JSP accepts any requests. [Figure 27.17](#) summarizes the three directive types. These directives are discussed in the next several subsections.

Figure 27.17. JSP directives.

(This item is displayed on page 1306 in the print version)

Directive	Description
<code>page</code>	Defines page settings for the JSP container to process.
<code>include</code>	Causes the JSP container to perform a translation-time insertion of another resource's content. As the JSP is translated into a servlet and compiled, the referenced file replaces the <code>include</code> directive and is translated as if it were originally part of the JSP.
<code>taglib</code>	Allows programmers to use new tags from tag libraries that encapsulate more complex functionality and simplify the coding of a JSP.

### 27.7.1. `page` Directive

The **page directive** specifies global settings for the JSP in the JSP container. There can be many `page` directives, provided that there is only one occurrence of each attribute. The only exception is the `import` attribute, which can be used repeatedly to `import` Java packages used in the JSP. [Figure 27.18](#) summarizes the attributes of the `page` directive.

Figure 27.18. Attributes of the page directive.

(This item is displayed on pages 1306 - 1307 in the print version)

Attribute	Description
<code>language</code>	The scripting language used in the JSP. Currently, the only valid value for this attribute is <code>java</code> .
<code>extends</code>	Specifies the class from which the translated JSP can inherit. This attribute must be a fully qualified class name.
<code>import</code>	Specifies a comma-separated list of fully qualified type names and/or packages that will be used in the current JSP. When the scripting language is <code>java</code> , the default import list is <code>java.lang.*</code> , <code>javax.servlet.*</code> , <code>javax.servlet.jsp.*</code> and <code>javax.servlet.http.*</code> . If multiple <code>import</code> properties are specified, the package names are placed in a list by the container.

Attribute	Description
<code>session</code>	Specifies whether the page participates in a session. The values for this attribute are <code>true</code> (participates in a sessionthe default) or <code>false</code> (does not participate in a session). When the page is part of a session, implicit object <code>session</code> is available for use in the page. Otherwise, <code>session</code> is not available, and using session in the scripting code results in a translation-time error.
<code>buffer</code>	Specifies the size of the output buffer used with the implicit object <code>out</code> . The value of this attribute can be <code>none</code> for no buffering or a value such as <code>8kb</code> (the default buffer size). The JSP specification indicates that the buffer used must be at least the size specified.
<code>autoFlush</code>	When set to <code>TRue</code> (the default), this attribute indicates that the output buffer used with implicit object <code>out</code> should be flushed automatically when the buffer fills. If set to <code>false</code> , an exception occurs if the buffer overflows. This attribute's value must be <code>TRue</code> if the buffer attribute is set to <code>none</code> .
<code>isThreadSafe</code>	Specifies whether the page is thread safe. If <code>true</code> (the default), the page is considered to be thread safe, and it can process multiple requests at the same time. If <code>false</code> , the servlet that represents the page implements interface <code>java.lang.SingleThreadModel</code> and only one request can be processed by that JSP at a time. The JSP standard allows multiple instances of a JSP to exist for JSPs that are not thread safe. This enables the container to handle requests more efficiently. However, this does not guarantee that resources shared across JSP instances are accessed in a thread-safe manner.
<code>info</code>	Specifies an information string that describes the page. This string is returned by the <code>getServletInfo</code> method of the servlet that represents the translated JSP. This method can be invoked through the JSP's implicit <code>page</code> object.
<code>errorPage</code>	Any exceptions in the current page that are not caught are sent to the error page for processing. The error-page implicit object <code>exception</code> references the original exception.
<code>isErrorPage</code>	Specifies whether the current page is an error page that will be invoked in response to an error on another page. If the attribute value is <code>true</code> , the implicit object <code>exception</code> is created and references the original exception that occurred. If <code>false</code> (the default), any use of the <code>exception</code> object in the page results in a translation-time error.
<code>contentType</code>	Specifies the MIME type of the data in the response to the client. The default type is <code>text/html</code> .
<code>pageEncoding</code>	Specifies the character encoding of the JSP page. The default value is ISO-8859-1.
<code>isELIgnored</code>	Specifies whether JSP container should evaluate expressions that use the <a href="#">Expression Language (EL)</a> a new feature in JSP 2.0 that allows JSP authors to create scriptless JSP pages. EL is typically used with JSP tag libraries, which are beyond the scope of this book. An EL expression has the form <code>\${ exp }</code> . If the attribute value is <code>true</code> , the EL expressions are ignored, which means that the JSP container does not evaluate the expressions at translation time. If <code>false</code> , the EL expressions are evaluated by the JSP container. For more information on EL, visit <a href="http://java.sun.com/developer/EJTechTips/2004/tt0126.html">java.sun.com/developer/EJTechTips/2004/tt0126.html</a>

## Common Programming Error 27.5

Providing multiple `page` directives with one or more repeated attributes in common is a JSP translation-time error, unless the values for all repeated attributes are identical. Also, providing a `page` directive with an attribute or value that is not recognized is a JSP translation-time error.

---

[Page 1306]

## Software Engineering Observation 27.9

According to the JSP specification, section 1.10.1, the `extends` attribute "should not be used without careful consideration as it restricts the ability of the JSP container to provide specialized superclasses that may improve on the quality of rendered service." Remember that a Java class can extend exactly one other class. If your JSP specifies an explicit superclass, the JSP container cannot translate your JSP into a subclass of one of the container application's own enhanced servlet classes.

---

[Page 1307]

## Common Programming Error 27.6

Using JSP implicit object `session` in a JSP that does not have its `page` directive attribute `session` set to `TRUE` is a translation-time error.

---

[Page 1308]

### 27.7.2. `include` Directive

The `include` directive includes the content of another resource once, at JSP translation time. The `include` directive has only one attribute `file` that specifies the URL of the resource to include. The difference between directive `include` and action `<jsp:include>` is noticeable only if the included content changes. For example, if the definition of an XHTML document changes after it is included with directive `include`, future invocations of the JSP will show the original content of the XHTML document, not the new content. In contrast, action `<jsp:include>` is processed in each request to the JSP. Therefore, changes to included content would be apparent in the next request to the JSP that uses action `<jsp:include>`.

JSP `includeDirective.jsp` (Fig. 27.19) reimplements `include.jsp` (Fig. 27.7) using `include` directives. To test `includeDirective.jsp` in Tomcat, copy it into the `jsp` directory created in Section 27.3. Open your Web browser and enter the following URL

`http://localhost:8080/jhttp6/jsp/includeDirective.jsp`

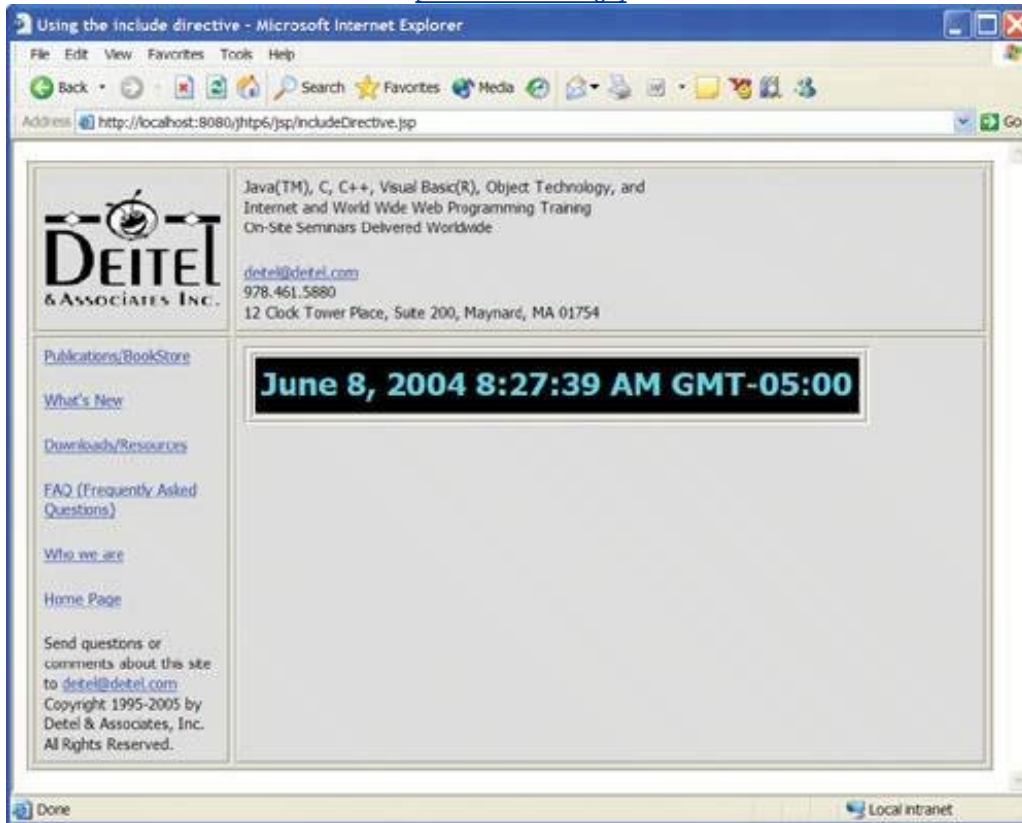

Figure 27.19. JSP `includeDirective.jsp` demonstrates including content at

## 27.8. Case Study: Guest Book

Our next example is a guest book that enables users to place their first name, last name and e-mail address into a guest-book database. After submitting their information, users see a Web page containing all the users in the guest book. Each e-mail address is displayed as a hyperlink that makes it possible to send an e-mail message to the person whose address it is. The example demonstrates action `<jsp:setProperty>`, the JSP page directive, JSP error pages, and using JDBC from a JSP.

The guest-book example consists of JavaBeans `GuestBean` (Fig. 27.20) and `GuestDataBean` (Fig. 27.21), and JSPs `guestBookLogin.jsp` (Fig. 27.22), `guestBookView.jsp` (Fig. 27.23) and `guestBookErrorPage.jsp` (Fig. 27.24). Sample outputs from this example are shown in Fig. 27.25. JavaBean `GuestBean` (Fig. 27.20) defines three guest properties `firstName`, `lastName` and `email`. Each property has *set* and *get* methods to manipulate the property.

Figure 27.20. `GuestBean` stores information for one guest.

(This item is displayed on pages 1319 - 1320 in the print version)

[\[View full size image\]](#)

[\[View full size image\]](#)

JavaBean `GuestDataBean` (Fig. 27.21) connects to the `guestbook` database and provides methods `getGuestList` and `addGuest` to manipulate the database. The `guestbook` database has a single table (`guests`) containing three columns (`firstName`, `lastName` and `email`). Each column stores `String` values. We provide a SQL script (`guestbook.sql`) with this example that can be used with the MySQL DBMS to create the `guestbook` database. For further details on creating a database with MySQL, refer back to [Section 25.7](#).

`GuestDataBean` constructor (lines 1629) loads the MySQL database driver, creates a `CachedRowSet` object using Sun's reference implementation `CachedRowSetImpl` and sets the properties of the `CachedRowSet`. Recall that `CachedRowSet` objects are disconnected rowsets, hence the database connection is automatically closed after the query is executed. Line 23 invokes method `setUrl` (from interface `RowSet`) to set the `CachedRowSet`'s database URL property. Line 24 invokes method `setUsername` (from interface `RowSet`) to set the `CachedRowSet`'s database username property. Line 25 invokes method `setPassword` (from interface `RowSet`) to set the `CachedRowSet`'s database password property. Lines 2829 invoke method `setCommand` (from interface `RowSet`) to set the `CachedRowSet`'s command property. Line 30 invokes method `execute` (from interface `RowSet`) to execute the query specified by the command property.

`GuestDataBean` method `getGuestList` (lines 3453) returns an `ArrayList` of `GuestBean` objects representing

the guests in the database. Line 38 invokes method `beforeFirst` (from interface `ResultSet`) to move the `CachedRowSet`'s cursor before the first row. Lines 4150 create the `GuestBean` objects for each row in the `CachedRowSet`.

`GuestDataBean` method `addGuest` (lines 5667) receives a `GuestBean` as an argument and uses the `GuestBean`'s properties as the arguments to insert a row to the `CachedRowSet`, which in turn propagates the changes to the underlying database. Recall from [Chapter 25](#) that a `CachedRowSet` is scrollable and updatable by default. Line 58 invokes the `CachedRowSet`'s `moveToInsertRow` method to remember the current row position and move the cursor to the `insert row` a special row in an updatable result set that allows programmers to insert new rows to the result set. Lines 6163 invoke the `CachedRowSet`'s `updateString` method to update the column values. Method `updateString` takes two arguments an `int` that specifies the column index and a `String` that specifies the column value. Line 64 invokes the `CachedRowSet`'s `insertRow` method to insert the row into the rowset. Line 65 invokes the `CachedRowSet`'s `moveToCurrentRow` method to move the cursor back to the current row the position before method `moveToInsertRow` was called. Line 66 invokes the `CachedRowSet`'s `acceptChanges` method to propagates the changes in the rowset to the underlying database.

---

[Page 1313]

Note that the `GuestDataBean`'s constructor, `getGuestList` method and `addGuest` method do not process potential exceptions. In the constructor, line 19 can throw a `ClassNotFoundException`, and the other statements can throw `SQLExceptions`. Similarly, `SQLExceptions` can be thrown from the bodies of methods `getGuestList` and `addGuest`. In this example, we purposely let any exceptions that occur get passed back to the JSP that invokes the `GuestDataBean`'s constructor or methods. This enables us to demonstrate JSP error pages. A JSP can include scriptlets that catch potential exceptions and process them. Exceptions that are not caught can be forwarded to a JSP error page for handling.

JavaServer Page `guestBookLogin.jsp` ([Fig. 27.22](#)) is a modified version of `forward1.jsp` ([Fig. 27.11](#)) that displays a `form` in which users can enter their first name, last name and e-mail address. When the user submits the `form`, `guestBookLogin.jsp` is requested again, so it can ensure that all the data values were entered. If they were not, the `guestBookLogin.jsp` responds with the `form` again, so the user can fill in missing field(s). If the user supplies all three pieces of information, `guestBookLogin.jsp` forwards the request to `guestBookView.jsp`, which displays the guest-book contents.

Line 8 of `guestBookLogin.jsp` uses the page directive, which defines information that is globally available in a JSP. In this case, the page directive's `errorPage` attribute is set to `guestBookErrorPage.jsp` ([Fig. 27.24](#)), indicating that all uncaught exceptions are forwarded to `guestBookErrorPage.jsp` for processing.

---

[Page 1315]

Lines 1114 define two `<jsp:useBean>` actions. Lines 1112 create an instance of `GuestBean` called `guest`. This bean has `page` scope it exists for use only in this page. Lines 1314 create an instance of `GuestDataBean` called `guestData`. This bean has `request` scope it exists for use in this page and any other page that helps process a single client request. Thus, when `guestBookLogin.jsp` forwards a request to `guestBookView.jsp`, the same `GuestDataBean` instance is still available for use in `guestBookView.jsp`.

Line 34 demonstrates setting a property of the `GuestBean` called `guest` with a request parameter value. The input elements in lines 48, 54 and 60 have the same names as the `GuestBean` properties. So we use action `<jsp:setProperty>`'s ability to match request parameters to properties by specifying `"*"` for attribute `property`. You can set the properties individually by replacing line 34 with the following lines:

```
<jsp:setProperty name = "guest" property = "firstName"
 param = "firstName" />

<jsp:setProperty name = "guest" property = "lastName"
 param = "lastName" />

<jsp:setProperty name = "guest" property = "email"
```

```
param = "email" />
```

If the request parameters had names that differed from `GuestBean`'s properties, the `param` attribute in each of the preceding `<jsp:setProperty>` actions could be changed to the appropriate request parameter name. Or you could make a call to the `set` method directly, like this:

```
<% guest.setFirstName(request.getParameter("firstName")); %>
```

JavaServer Page `guestBookView.jsp` (Fig. 27.23) outputs an XHTML document containing the guest-book entries in tabular format. Lines 810 define three `page` directives. Line 8 specifies that the error page for this JSP is `guestBookErrorPage.jsp`. Line 9 indicates that classes from package `java.util` are used in this JSP, and line 10 indicates that classes from our package `com.deitel.jhtp6.jsp.beans` are also used.

---

[Page 1317]

Lines 1314 specify a `<jsp:useBean>` action that declares a reference to a `GuestDataBean` object. If a `GuestDataBean` object already exists, the action returns a reference to the existing object. Otherwise, the action creates a `GuestDataBean` for use in this JSP. Lines 4553 define a scriptlet that gets the guest list from the `GuestDataBean` and begins a loop to output the entries. Lines 5461 combine fixed template text with JSP expressions to create rows in the table of guest-book data that will be displayed on the client. The scriptlet at lines 6264 terminates the loop that begins at line 50.

JavaServer Page `guestBookErrorPage.jsp` (Fig. 27.24) outputs an XHTML document containing an error message based on the type of exception that causes this error page to be invoked. Lines 810 define several `page` directives. Line 8 sets `page` directive attribute `isErrorPage`. Setting this attribute to `TRUE` makes the JSP an error page and enables access to the JSP implicit object `exception` that refers to an exception object indicating the problem that occurred.

---

[Page 1319]

Lines 2652 define scriptlets that determine the type of exception that occurred and begin outputting an appropriate error message with fixed template data. The actual error message from the exception is output at line 60.

Figure 27.25 shows sample interactions between the user and the JSPs in the guest book example. In the first two rows of output, separate users entered their first name, last name and e-mail. In each case, the current contents of the guest book are returned and displayed for the user. In the final interaction, a third user specified an e-mail address that already existed in the database. The e-mail address is the primary key in the `guests` table of the `guestbook` database, so its values must be unique. Thus, the database prevents the new record from being inserted, and an exception occurs. The exception is forwarded to `guestBookErrorPage.jsp` for processing, which results in the last screen capture.

---

[Page 1320]

To test the guest book in Tomcat, copy `guestBookLogin.jsp`, `guestBookView.jsp` and `guestBookErrorPage.jsp` into the `jsp` directory created in Section 27.3. Copy `GuestBean.class` and `GuestDataBean.class` into the `jhtp6` Web application's `WEBINF\classes\com\deitel\jhtp6\beans` directory in Tomcat. [Note: This example will work only if the proper package directory structure for `GuestBean` and `GuestDataBean` is defined in the `classes` directory. These classes are declared in package `com.deitel.jhtp6.jsp.beans`.] Create the database by running the `guestbook.sql` script included with this example on the CD that accompanies this book. For further details on creating a database with MySQL, refer back to Section 25.7. Open your Web browser and enter the following URL to test `guestBookLogin.jsp`:

<http://localhost:8080/jhttp6/jsp/guestBookLogin.jsp>

## 27.9. Wrap-Up

In this chapter, you learned several JSP components: implicit objects, scripting elements, standard actions and directives. You saw JSP examples that use these components to separate presentation from business logic and learned that logic can be placed in a JSP via scripting elements. You also learned how to use the `CachedRowSet` to manipulate a MySQL database in a JavaBean object, then access the JavaBean object in a JSP page. In the next chapter, we summarize how to display formatted output with various format characters and flags. We also demonstrate how to format output with class `Formatter`.

This Web programming site concentrates on resources for JSP programmers. It includes software, tutorials, articles, sample code, references and links to other JSP and Web programming resources.

## Summary

- JavaServer Pages (JSPs) are an extension of servlet technology.
  - JSPs enable Web application programmers to create dynamic content by reusing predefined components and by interacting with components using server-side scripting.
  - JSP programmers can create custom tag libraries that enable Web page designers who are not familiar with Java to enhance their Web pages with powerful dynamic content and processing capabilities.
  - Classes and interfaces specific to JavaServer Pages programming are located in packages `javax.servlet.jsp` and `javax.servlet.jsp.tagext`.
  - There are four key components to JSPs: directives, actions, scriptlets and tag libraries.
  - Directives specify global information that is not associated with a particular JSP request.
- 

- Actions encapsulate functionality in predefined tags that programmers can embed in a JSP.
- Scriptlets enable programmers to insert Java code that interacts with components in a JSP (and possibly other Web application components) to perform request processing.
- Tag libraries are part of the tag extension mechanism that enables programmers to create new tags that encapsulate complex Java functionality.
- JSPs normally include XHTML or XML markup. Such markup is known as fixed-template data or fixed-template text.
- Programmers tend to use JSPs when most of the content sent to the client is fixed-template data and only a small portion of the content is generated dynamically with Java code.
- Programmers use servlets when a small portion of the content is fixed-template data.
- The request/response mechanism and life cycle of a JSP are the same as those of a servlet.
- JSPs can define methods `jspInit` and `jspDestroy` that are invoked when the container initializes a JSP and when the container terminates a JSP, respectively.
- Implicit objects provide programmers with servlet capabilities in the context of a JavaServer Page.
- Implicit objects have four scopes: application, page, request and session.
- Objects with application scope are part of the JSP and servlet container application. Objects with page scope exist only as part of the page in which they are used. Each page has its own instances of the page-scope implicit objects. Objects in request scope exist for the duration of the request. Request-scope objects go out of scope when request processing completes with a response to the client. Objects in session scope exist for the client's entire browsing session.
- JSP scripting components include scriptlets, comments, expressions, declarations and escape sequences.
- JSP comments are delimited by `<%--` and `--%>`.
- XHTML comments are delimited by `<!--` and `-->`.

- Java's end-of-line comments (//) and traditional comments (delimited by /\* and \*/) can be used inside scriptlets.
- JSP comments and scripting-language comments are ignored and do not appear in a response.
- A JSP expression, delimited by <%= and %>, contains a Java expression that is evaluated when a client requests the JSP containing the expression. The container converts the result of a JSP expression to a `String` object, then outputs the `String` as part of the response to the client.
- Declarations, delimited by <%! and %>, enable a JSP programmer to declare variables and methods. Variables become instance variables of the class that represents the translated JSP. Similarly, methods become members of the class that represents the translated JSP.
- Special characters or character sequences that the JSP container normally uses to delimit JSP code can be included in a JSP as literal characters in scripting elements, fixed-template data and attribute values by using escape sequences.
- JavaServer Pages support two include mechanisms: the `<jsp:include>` action and the `include` directive.
- Action `<jsp:include>` enables dynamic content to be included in a JSP. If the included resource changes between requests, the next request to that JSP includes the new content of the included resource.
- The `include` directive is processed once, at JSP translation time, and causes the content to be copied into the JSP. If the included resource changes, the new content will not be reflected in the JSP that used the include directive unless that JSP is recompiled.

---

[Page 1323]

- Action `<jsp:forward>` enables a JSP to forward the processing of a request to a different resource. Processing of the request by the original JSP terminates as soon as the request is forwarded.
- Action `<jsp:param>` specifies name-value pairs of information that are passed to the `include`, `forward` and `plugin` actions. Every `<jsp:param>` action has two required attributes `name` and `value`. If a `param` action specifies a parameter that already exists in the request, the new value for the parameter takes precedence over the original value. All the values for that parameter can be obtained with the JSP implicit object `request`'s `getParameterValues` method, which returns an array of `Strings`.
- Action `<jsp:useBean>` enables a JSP to manipulate a Java object. This action can be used to create a Java object for use in the JSP or to locate an existing object.
- Like JSP implicit objects, objects specified with action `<jsp:useBean>` have `page`, `request`, `session` or `application` scope that indicates where they can be used in a Web application.
- Action `<jsp:getProperty>` obtains the value of a `JavaBean`'s property. Action `<jsp:getProperty>` has two attributes `name` and `property` that specify the bean object to manipulate and the property to get.
- `JavaBean` property values can be set with action `<jsp:setProperty>`. Request parameters can be used to set properties of primitive types `boolean`, `byte`, `char`, `short`, `int`, `long`, `float` and `double` and `java.lang` types `String`, `Boolean`, `Byte`, `Character`, `Short`, `Integer`, `Long`, `Float` and `Double`.
- The `page` directive defines information that is globally available in a JSP. Directives are delimited by <%@ and %>. The page directive's `errorPage` attribute indicates where all uncaught exceptions are forwarded for processing.
- Action `<jsp:setProperty>` has the ability to match request parameters to properties of the same name in a bean by specifying "\*" for attribute `property`.
- Attribute `import` of the `page` directive enables programmers to specify Java classes and packages that are used in the context of a JSP.
- If the attribute `isErrorPage` of the `page` directive is set to `true`, the JSP is an error page. This condition

enables access to the JSP implicit object `exception` that refers to an exception object indicating the problem that occurred.

- Directives are messages to the JSP container that enable the programmer to specify page settings (e.g., the error page), to include content from other resources and to specify custom tag libraries that can be used in a JSP. Directives are processed at the time a JSP is translated into a servlet and compiled. Thus, they do not produce any immediate output.
- The `page` directive specifies global settings for a JSP in the JSP container. There can be many `page` directives, provided that there is only one occurrence of each attribute. The exception to this rule is the `import` attribute, which can be used repeatedly to import Java packages.

## Self-Review Exercises

27.1 Fill in the blanks in each of the following statements:

- a. Action \_\_\_\_\_ has the ability to match request parameters to properties of the same name in a bean by specifying "\*" for attribute `property`.
- b. There are four key components to JSPs: \_\_\_\_\_, \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.
- c. The implicit objects have four scopes: \_\_\_\_\_, \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.
- d. The \_\_\_\_\_ directive is processed once at JSP translation time and causes content to be copied into the JSP.
- e. Classes and interfaces specific to JavaServer Pages programming are located in packages \_\_\_\_\_ and \_\_\_\_\_.

---

[Page 1325]

- f. JSPs normally execute as part of a Web server that is referred to as the \_\_\_\_\_.
- g. JSP scripting components include \_\_\_\_\_, \_\_\_\_\_, \_\_\_\_\_, \_\_\_\_\_ and \_\_\_\_\_.

27.2 State whether each of the following is *true* or *false*. If *false*, explain why.

- a. An object with page scope exists in every JSP of a particular Web application.
- b. Directives specify global information that is not associated with a particular JSP request.
- c. Action `<jsp:include>` is evaluated once at page translation time.
- d. Like XHTML comments, JSP comments and script-language comments appear in the response to the client.
- e. Objects with application scope are part of a particular Web application.
- f. Each page has its own instances of the page-scope implicit objects.
- g. Action `<jsp:setProperty>` has the ability to match request parameters to properties of the same name in a bean by specifying "\*" for attribute `property`.
- h. Objects with session scope exist for the client's entire browsing session.

## Answers to Self-Review Exercises

- [27.1](#) a) `<jsp:setProperty>`. b) directives, actions, scripting elements, tag libraries. c) application, page, request, session. d) `include`. e) `javax.servlet.jsp`, `javax.servlet.jsp.tagext`. f) JSP container. g) scriptlets, comments, expressions, declarations, escape sequences.
- [27.2](#) a) False. Objects with page scope exist only as part of the page in which they are used. b) True. c) False. Action `<jsp:include>` enables dynamic content to be included in a JavaServer Page. d) False. JSP comments and script-language comments are ignored and do not appear in the response. e) False. Objects with application scope are part of the JSP container application. f) True. g) True. h) True.

## Exercises

- 27.3 Write a JSP page to output the string "Hello world!" ten times.
- 27.4 Modify [Exercise 26.6](#) to run as a JSP page.
- 27.5 Rewrite [Figure 27.15](#) to provide a form that allow users to select a book title and view the book's cover. Use a JSP expression instead of the `getProperty` JSP tag.
- 27.6 Create a JSP- and JDBC-based address book. Use the guest-book example of [Fig. 27.20](#) through [Fig. 27.24](#) as a guide. Your address book should allow the user to insert entries and search for entries. [*Note:* If you are not familiar with XHTML and CSS, refer to the chapters from our book *Internet & World Wide Web HTTP, 3/e* Introduction to XHTML: Part 1, Introduction to XHTML: Part 2 and Cascading Style Sheets (CSS), which are included as PDF documents on the CD that accompanies this book.]
- 27.7 Reimplement the Web application of [Fig. 26.21](#) (favorite animal survey) using JSPs. [*Note:* If you are not familiar with XHTML and CSS, refer to the chapters from our book *Internet & World Wide Web HTTP, 3/e* Introduction to XHTML: Part 1, Introduction to XHTML: Part 2 and Cascading Style Sheets (CSS), which are included as PDF documents on the CD that accompanies this book.]
- 27.8 Modify your solution to [Exercise 27.7](#) to allow the user to see the survey results without responding to the survey. [*Note:* If you are not familiar with XHTML and CSS, refer to the chapters from our book *Internet & World Wide Web HTTP, 3/e* Introduction to XHTML: Part 1, Introduction to XHTML: Part 2 and Cascading Style Sheets (CSS), which are included as PDF documents on the CD that accompanies this book.]

# Chapter 28. Formatted Output

*All the news that's fit to print.*

Adolph S. Ochs

*What mad pursuit? What struggle to escape?*

John Keats

*Remove not the landmark on the boundary of the fields.*

Amenehope

## OBJECTIVES

In this chapter you will learn:

- To understand input and output streams.
- To use `printf` formatting.
- To print with field widths and precisions.
- To use formatting flags in the `printf` format string.
- To print with an argument index.
- To output literals and escape sequences.
- To format output with class `Formatter`.

## Outline

[28.1](#) Introduction

[28.2](#) Streams

[28.3](#) Formatting Output with `printf`

[28.4](#) Printing Integers

[28.5](#) Printing Floating-Point Numbers

[28.6](#) Printing Strings and Characters

[28.7](#) Printing Dates and Times

[28.8](#) Other Conversion Characters

[28.9](#) Printing with Field Widths and Precisions

[28.10](#) Using Flags in the `printf` Format String

[28.11](#) [Printing with Argument Indices](#)

[28.12](#) [Printing Literals and Escape Sequences](#)

[28.13](#) [Formatting Output with Class `Formatter`](#)

[◀ PREV](#)

[NEXT ▶](#)

## 28.1. Introduction

An important part of the solution to any problem is the presentation of the results. In this chapter, we discuss the formatting features of method `printf` and class `Formatter` (package `java.util`). Method `printf` formats and outputs data to the standard output stream `System.out`. Class `Formatter` formats and outputs data to a specified destination, such as a string or a file output stream.

Many features of `printf` were discussed earlier in the text. This chapter summarizes those features and introduces others, such as displaying date and time data in various formats, reordering output based on the index of the argument and displaying numbers and strings with various flags.

## 28.2. Streams

Input and output are usually performed with streams, which are sequences of bytes. In input operations, the bytes flow from a device (e.g., a keyboard, a disk drive, a network connection) to main memory. In output operations, bytes flow from main memory to a device (e.g., a display screen, a printer, a disk drive, a network connection, etc.).

When program execution begins, three streams are connected to the program automatically. Normally, the standard input stream is connected to the keyboard, and the standard output stream is connected to the screen. A third stream, the **standard error stream** (`System.err`), is typically connected to the screen and is used to output error messages to the screen so they can be viewed immediately even when the standard output stream is writing into a file. Operating systems typically allow these streams to be redirected to other devices. Streams are discussed in detail in [Chapter 14](#), Files and Streams, and [Chapter 24](#), Networking.

## 28.3. Formatting Output with `printf`

Precise output formatting is accomplished with `printf`. [*Note:* J2SE 5.0 borrowed this feature from the C programming language.] Method `printf` can perform the following formatting capabilities, each of which is discussed in this chapter:

1. Rounding floating-point values to an indicated number of decimal places.
2. Aligning a column of numbers with decimal points appearing one above the other.
3. Right justification and left justification of outputs.
4. Inserting literal characters at precise locations in a line of output.
5. Representing floating-point numbers in exponential format.
6. Representing integers in octal and hexadecimal format. (See [Appendix E](#), Number Systems, for more information on octal and hexadecimal values.)
7. Displaying all types of data with fixed-size field widths and precisions.
8. Displaying dates and times in various formats.

Every call to `printf` supplies as the first argument a **format string** that describes the output format. The format string may consist of **fixed text** and **format specifiers**. Fixed text is output by `printf` just as it would be output by `System.out` methods `print` or `println`. Each format specifier is a placeholder for a value and specifies the type of data to output. Format specifiers also may include optional formatting information.

In the simplest form, each format specifier begins with a percent sign (`%`) and is followed by a **conversion character** that represents the data type of the value to output. For example, the format specifier `%s` is a placeholder for a string, and the format specifier `%d` is a placeholder for an `int` value. The optional formatting information is specified between the percent sign and the conversion character. The optional formatting information includes an argument index, flags, field width and precision. We define each of these and show examples of them throughout this chapter.

# 28.4. Printing Integers

An integer is a whole number, such as 776, 0 or 52, that contains no decimal point. Integer values are displayed in one of several formats. [Figure 28.1](#) describes the [integral conversion characters](#).

Figure 28.1. Integer conversion characters.

Conversion character	Description
d	Display a decimal (base 10) integer.
o	Display an octal (base 8) integer.
x or X	Display a hexadecimal (base 16) integer. X causes the digits 09 and the letters AF to be displayed and x causes the digits 09 and af to be displayed.

[Figure 28.2](#) prints an integer using each of the integral conversions. In lines 910, note that the plus sign is not displayed by default, but the minus sign is. Later in this chapter ([Fig. 28.14](#)) we will see how to force plus signs to print.

Figure 28.2. Using integer conversion characters.

```
1 // Fig. 28.2: IntegerConversionTest.java
2 // Using the integral conversion characters.
3
4 public class IntegerConversionTest
5 {
6 public static void main(String args[])
7 {
8 System.out.printf("%d\n", 26);
9 System.out.printf("%d\n", +26);
10 System.out.printf("%d\n", -26);
11 System.out.printf("%o\n", 26);
12 System.out.printf("%x\n", 26);
13 System.out.printf("%X\n", 26);
14 } // end main
15 } // end class IntegerConversionTest
```

```
26
26
-26
32
1a
1A
```

The `printf` method has the form

```
printf(format-string, argument-list);
```

where *format-string* describes the output format, and *argument-list* contains the values that correspond to each format specifier in *format-string*. There can be many format specifiers in one format string.

Each format string in lines 810 specifies that `printf` should output a decimal integer (`%d`) followed by a newline character. At the format specifier's position, `printf` substitutes the value of the first argument after the format string. If the format string contained multiple format specifiers, at each subsequent format specifier's position, `printf` would substitute the value of the next argument in the argument list. The `%o` format specifier in line 11 outputs the integer in octal format. The `%x` format specifier in line 12 outputs the integer in hexadecimal format. The `%X` format specifier in line 13 outputs the integer in hexadecimal format with capital letters.

[< PREV](#)[NEXT >](#)

## 28.5. Printing Floating-Point Numbers

A floating-point value contains a decimal point, as in `33.5`, `0.0` or `-657.983`. Floating-point values are displayed in one of several formats. [Figure 28.3](#) describes the floating-point conversions. The **conversion character** `e` and `E` displays floating-point values in **computerized scientific notation** (also called **exponential notation**). Exponential notation is the computer equivalent of the scientific notation used in mathematics. For example, the value `150.4582` is represented in scientific notation in mathematics as

$$1.504582 \times 10^2$$

Figure 28.3. Floating-point conversion characters.

(This item is displayed on page 1330 in the print version)

Conversion character	Description
<code>e</code> or <code>E</code>	Display a floating-point value in exponential notation. When conversion character <code>E</code> is used, the output is displayed in uppercase letters.
<code>f</code>	Display a floating-point value in decimal format.
<code>g</code> or <code>G</code>	Display a floating-point value in either the floating-point format <code>f</code> or the exponential format <code>e</code> based on the magnitude of the value. If the magnitude is less than $10^3$ , or greater than or equal to $10^7$ , the floating-point value is printed with <code>e</code> (or <code>E</code> ). Otherwise, the value is printed in format <code>f</code> . When conversion character <code>G</code> is used, the output is displayed in uppercase letters.
<code>a</code> or <code>A</code>	Display a floating-point number in hexadecimal format. When conversion character <code>A</code> is used, the output is displayed in uppercase letters.

and is represented in exponential notation as

$$1.504582e+02$$

in Java. This notation indicates that `1.504582` is multiplied by `10` raised to the second power (`e+02`). The `e` stands for "exponent."

Values printed with the conversion characters `e`, `E` and `f` are output with six digits of precision to the right of the decimal point by default (e.g., `1.045921`) other precisions must be specified explicitly. For values printed with the conversion character `g`, the precision represents the total number of digits displayed, excluding the exponent. The default is six digits (e.g., `12345678.9` is displayed as `1.23457e+07`). **Conversion character** `f` always prints at least one digit to the left of the decimal point. Conversion character `e` and `E` print lowercase `e` and uppercase `E` preceding the exponent and always print exactly one digit to the left of the decimal point. Rounding occurs if the value being formatted has more significant digits than the precision.

**Conversion character g** (or **G**) prints in either **e** (**E**) or **f** format, depending on the floating-point value. For example, the values 0.0000875, 87500000.0, 8.75, 87.50 and 875.0 are printed as 8.750000e-05, 8.750000e+07, 8.750000, 87.500000 and 875.000000 with the conversion character **g**. The value 0.0000875 uses **e** notation because the magnitude is less than 10<sup>-3</sup>. The value 87500000.0 uses **e** notation because the magnitude is greater than 10<sup>7</sup>. [Figure 28.4](#) demonstrates each of the floating-point conversion characters.

Figure 28.4. Using floating-point conversion characters.

12345678.900000
1.23457e+07
1.23457E+07
```

## 28.6. Printing Strings and Characters

The `c` and `s` conversion characters are used to print individual characters and strings, respectively. Conversion character `s` can also print objects with the results of implicit calls to method `toString`. **Conversion character `c`** and **`C`** requires a `char` argument. **Conversion character `s`** and **`S`** can take a `String` or any `Object` (this includes all subclasses of `Object`) as an argument. When an object is passed to the conversion character `s`, the program implicitly uses the object's `toString` method to obtain the `String` representation of the object. When conversion characters `c` and `s` are used, the output is displayed in uppercase letters. The program shown in [Fig. 28.5](#) displays characters, strings and objects with conversion characters `c` and `s`. Note that autoboxing occurs at line 10 when an `int` constant is assigned to an `Integer` object. Line 15 associates an `Integer` object argument to the conversion character `s`, which implicitly invokes the `toString` method to get the integer value. Note that you can also output an `Integer` object using the `%d` format specifier. In this case, the `int` value in the `Integer` object will be unboxed and output.

Figure 28.5. Using character and string conversion characters.

(This item is displayed on page 1332 in the print version)

```
1 // Fig. 28.5: CharStringConversion.java
2 // Using character and string conversion characters.
3
4 public class CharStringConversion
5 {
6 public static void main(String args[])
7 {
8 char character = 'A'; // initialize char
9 String string = "This is also a string"; // String object
10 Integer integer = 1234; // initialize integer (autoboxing)
11
12 System.out.printf("%c\n", character);
13 System.out.printf("%s\n", "This is a string");
14 System.out.printf("%s\n", string);
15 System.out.printf("%S\n", string);
16 System.out.printf("%s\n", integer); // implicit call to toString
17 } // end main
18 } // end class CharStringConversion
```

```

This is a string
This is also a string
THIS IS ALSO A STRING
1234
```

---

## Common Programming Error 28.1

*Using `%c` to print a string causes an `Illegal FormatConversionException` a string cannot be converted to a character.*

[< PREV](#)[NEXT >](#)

# 28.7. Printing Dates and Times

With the **conversion character** `t` or `T`, we can print dates and times in various formats. Conversion character `t` or `T` is always followed by a **conversion suffix character** that specifies the date and/or time format. When conversion character `T` is used, the output is displayed in uppercase letters. [Figure 28.6](#) lists the common conversion suffix characters for formatting **date and time compositions** that display both the date and the time. [Figure 28.7](#) lists the common conversion suffix characters for formatting dates. [Figure 28.8](#) lists the common conversion suffix characters for formatting times. To view the complete list of conversion suffix characters, visit the Web site [java.sun.com/j2se/5.0/docs/api/java/util/Formatter.html](http://java.sun.com/j2se/5.0/docs/api/java/util/Formatter.html).

Figure 28.6. Date and time composition conversion suffix characters.

(This item is displayed on page 1332 in the print version)

Conversion suffix character	Description
<code>c</code>	Display date and time formatted as <code>day month date hour:minute:second time-zone year</code> with three characters for day and month, two digits for date, hour, minute and second and four digits for yearfor example, <code>Wed Mar 03 16:30:25 GMT-05:00 2004</code> . The 24-hour clock is used. In this example, <code>GMT-05:00</code> is the time zone.
<code>F</code>	Display date formatted as <code>year-month-date</code> with four digits for the year and two digits each for the month and the date (e.g., <code>2004-05-04</code> ).
<code>D</code>	Display date formatted as <code>month/day/year</code> with two digits each for the month, day and year (e.g., <code>03/03/04</code> ).
<code>r</code>	Display time formatted as <code>hour:minute:second AM PM</code> with two digits each for the hour, minute and second (e.g., <code>04:30:25 PM</code> ). The 12-hour clock is used.
<code>R</code>	Display time formatted as <code>hour:minute</code> with two digits each for the hour and minute (e.g., <code>16:30</code> ). The 24-hour clock is used.
<code>T</code>	Display time formatted as <code>hour:minute:second</code> with two digits for the hour, minute and second (e.g., <code>16:30:25</code> ). The 24-hour clock is used.

Figure 28.7. Date formatting conversion suffix characters.

Conversion suffix character	Description
<code>A</code>	Display full name of the day of the week (e.g., <code>Wednesday</code> ).
<code>a</code>	Display the three-character short name of the day of the week (e.g., <code>Wed</code> ).
<code>B</code>	Display full name of the month (e.g., <code>March</code> ).

Conversion suffix character	Description
<code>b</code>	Display the three-character short name of the month (e.g., <code>Mar</code> ).
<code>d</code>	Display the day of the month with two digits, padding with leading zeros as necessary (e.g., <code>03</code> ).
<code>m</code>	Display the month with two digits, padding with leading zeros as necessary (e.g., <code>07</code> ).
<code>e</code>	Display the day of month without leading zeros (e.g., <code>3</code> ).
<code>Y</code>	Display the year with four digits (e.g., <code>2004</code> ).
<code>y</code>	Display the last two digits of the year with leading zeros as necessary (e.g., <code>04</code> ).
<code>j</code>	Display the day of the year with three digits, padding with leading zeros as necessary (e.g., <code>016</code> ).

Figure 28.8. Time formatting conversion suffix characters.

Conversion suffix character	Description
<code>H</code>	Display hour in 24-hour clock with a leading zero as necessary (e.g., <code>16</code> ).
<code>I</code>	Display hour in 12-hour clock with a leading zero as necessary (e.g., <code>04</code> ).
<code>k</code>	Display hour in 24-hour clock without leading zeros (e.g., <code>16</code> ).
<code>l</code>	Display hour in 12-hour clock without leading zeros (e.g., <code>4</code> ).
<code>M</code>	Display minute with a leading zero as necessary (e.g., <code>06</code> ).
<code>S</code>	Display second with a leading zero as necessary (e.g., <code>05</code> ).
<code>Z</code>	Display the abbreviation for the time zone (e.g., <code>GMT-05:00</code> , stands for Eastern Standard Time, which is 5 hours behind Greenwich Mean Time).
<code>p</code>	Display morning or afternoon marker in lower case (e.g., <code>pm</code> ).
<code>P</code>	Display morning or afternoon marker in upper case (e.g., <code>PM</code> ).

[Figure 28.9](#) uses the conversion character `t` together with the conversion suffix characters to display dates and times in various formats. Conversion character `t` requires the corresponding argument to be of type `long`, `Long`, `Calendar` or `Date` (both in package `java.util`) objects of each of these classes can represent dates and times. Class `Calendar` is the preferred class for this purpose because some constructors and methods in class `Date` are replaced by those in class `Calendar`. Line 10 invokes `static` method `getInstance` of `Calendar` to obtain a calendar with the current date and time. Lines 1317, 2022 and 2526 use this `Calendar` object in `printf` statements as the value to be formatted with conversion character `t`. Note that lines 2022 and 2526 use the optional `argument index` ("`%1s`") to indicate that all format specifiers in the format string use the first argument after the format string in the argument list. You will learn more about argument indices in [Section 28.11](#). Using the argument index eliminates the need to repeatedly list the same argument.

Figure 28.9. Formatting dates and times with conversion character **t**.

```

## 28.8. Other Conversion Characters

The remaining conversion characters are `b`, `B`, `h`, `H`, `%` and `n`. These are described in [Fig. 28.10](#).

Figure 28.10. Other conversion specifiers.

Conversion character	Description
<code>b</code> or <code>B</code>	Print <code>"true"</code> or <code>"false"</code> for the value of a <code>boolean</code> or <code>Boolean</code> . These conversion characters can also format the value of any reference. If the reference is non- <code>null</code> , <code>"true"</code> is output; otherwise, <code>"false"</code> is output. When conversion character <code>B</code> is used, the output is displayed in uppercase letters.
<code>h</code> or <code>H</code>	Print the string representation of an object's hash code value in hexadecimal format. If the corresponding argument is a <code>null</code> reference, <code>"null"</code> is printed. When conversion character <code>H</code> is used, the output is displayed in uppercase letters.
<code>%</code>	Print the percent character.
<code>n</code>	Print the platform-specific line separator (e.g., <code>\r\n</code> on Windows or <code>\n</code> on UNIX/LINUX).

Lines 910 of [Fig. 28.11](#) use `%b` to print the value of boolean values `false` and `true`. Line 11 associates a `String` to `%b`, which returns `true` because it is not `null`. Line 12 associates a `null` object to `%B`, which displays `FALSE` because `test` is `null`. Lines 1314 use `%h` to print the string representations of the hash code values for strings `"hello"` and `"Hello"`. These values could be used to store or locate the strings in a `Hashtable` or `HashMap` (both discussed in [Chapter 19](#), Collections). Note that the hash code values for these two strings differ because one string starts with a lowercase letter and the other starts with an uppercase letter. Line 15 uses `%H` to print `null` in uppercase letters. The last two `printf` statements (lines 1617) use `%%` to print the `%` character in a string and `%n` to print a platform-specific line separator.

Figure 28.11. Using the `b`, `B`, `h`, `H`, `%` and `n` conversion characters.

(This item is displayed on page 1336 in the print version)

```

HashCode of "Hello" is 42628b2
HashCode of null is NULL
Printing a % in a format string
Printing a new line
next line starts here

```

## Common Programming Error 28.2

*Trying to print a literal percent character using % rather than %% in the format string might cause a difficult-to-detect logic error. When % appears in a format string, it must be followed by a conversion character in the string. The single percent could accidentally be followed by a legitimate conversion character, thus causing a logic error.*

## 28.9. Printing with Field Widths and Precisions

The exact size of a field in which data is printed is specified by a [field width](#). If the field width is larger than the data being printed, the data will be right justified within that field by default. (We demonstrate left justification in [Section 28.10](#)) The programmer inserts an integer representing the field width between the percent sign (%) and the conversion character (e.g., %4d) in the format specifier. [Figure 28.12](#) prints two groups of five numbers each, right justifying those numbers that contain fewer digits than the field width. Note that the field width is increased to print values wider than the field and that the minus sign for a negative value uses one character position in the field. Also, if no field width is specified, the data prints in exactly as many positions as it needs. Field widths can be used with all format specifiers except the line separator (%n).

---

```

### Common Programming Error 28.3

*Not providing a sufficiently large field width to handle a value to be printed can offset other data being printed and produce confusing outputs. Know your data!*

Method `printf` also provides the ability to specify the precision with which data is printed. Precision has different meanings for different types. When used with floating-point conversion characters `e` and `f`, the precision is the number of digits that appear after the decimal point. When used with conversion character `g`, the precision is the maximum number of significant digits to be printed. When used with conversion character `s`, the precision is the maximum number of characters to be written from the string. To use precision, place between the percent sign and the conversion specifier a decimal point (.) followed by an integer representing the precision. [Figure 28.13](#) demonstrates the use of precision in format strings. Note that when a floating-point value is printed with a precision smaller than the original number of decimal places in the value, the value is rounded. Also note that the format specifier `%.3g` indicates that the total number of digits used to display the floating-point value is 3. Because the value has three digits to the left of the decimal point, the value is rounded to the ones position.

Figure 28.13. Using precision for floating-point numbers and strings.

(This item is displayed on page 1338 in the print version)

```

1 // Fig. 28.13: PrecisionTest.java
2 // Using precision for floating-point numbers and strings.
3 public class PrecisionTest
4 {
5 public static void main(String args[])
6 {
7 double f = 123.94536;
8 String s = "Happy Birthday";
9
10 System.out.printf("Using precision for floating-point numbers\n");
11 System.out.printf("\t%.3f\n\t%.3e\n\t%.3g\n\n", f, f, f);
12
13 System.out.printf("Using precision for strings\n");
14 System.out.printf("\t%.11s\n", s);
15 } // end main
16 } // end class PrecisionTest

```

```

Using precision for floating-point numbers
 123.945
 1.239e+02
 124
Using precision for strings
 Happy Birth

```

The field width and the precision can be combined by placing the field width, followed by a decimal point, followed by a precision between the percent sign and the conversion character, as in the statement

```
printf("%9.3f", 123.456789);
```

which displays `123.457` with three digits to the right of the decimal point right justified in a nine-digit field this number will be preceded in its field by two blanks.

## 28.10. Using Flags in the printf Format String

Various flags may be used with method `printf` to supplement its output formatting capabilities. Seven flags are available for use in format strings ([Fig. 28.14](#)).

Figure 28.14. Format string flags.

(This item is displayed on page 1338 in the print version)

Flag	Description
- (minus sign)	Left justify the output within the specified field.
+ (plus sign)	Display a plus sign preceding positive values and a minus sign preceding negative values.
<i>space</i>	Print a space before a positive value not printed with the + flag.
#	Prefix 0 to the output value when used with the octal conversion character o.
	Prefix 0x to the output value when used with the hexadecimal conversion character x.
0 (zero)	Pad a field with leading zeros.
, (comma)	Use the locale-specific thousands separator (i.e., ',' for U.S. locale) to display decimal and floating-point numbers.
(	Enclose negative numbers in parentheses.

To use a flag in a format string, place the flag immediately to the right of the percent sign. Several flags may be used in the same format specifier. [Figure 28.15](#) demonstrates right justification and left justification of a string, an integer, a character and a floating-point number. Note that line 9 serves as a counting mechanism for the screen output.

Figure 28.15. Right justifying and left justifying values.

(This item is displayed on page 1339 in the print version)

```

1 // Fig. 28.15: MinusFlagTest.java
2 // Right justifying and left justifying values.
3
4 public class MinusFlagTest
5 {
6 public static void main(String args[])
7 {
8 System.out.println("Columns:");
9 System.out.println("0123456789012345678901234567890123456789\n");
10 System.out.printf("%10s%10d%10c%10f\n\n", "hello", 7, 'a', 1.23);
11 System.out.printf(
12 "%-10s%-10d%-10c%-10f\n", "hello", 7, 'a', 1.23);
13 } // end main
14 } // end class MinusFlagTest

```

```

Columns:
0123456789012345678901234567890123456789
 hello 7 a 1.230000
hello 7 a 1.230000

```

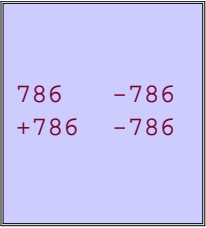

[Figure 28.16](#) prints a positive number and a negative number, each with and without the **+** flag. Note that the minus sign is displayed in both cases, but the plus sign is displayed only when the **+** flag is used.

Figure 28.16. Printing numbers with and without the **+** flag.

```

1 // Fig. 28.16: PlusFlagTest.java
2 // Printing numbers with and without the + flag.
3
4 public class PlusFlagTest
5 {
6 public static void main(String args[])
7 {
8 System.out.printf("%d\t%d\n", 786, -786);
9 System.out.printf("%+d\t%+d\n", 786, -786);
10 } // end main
11 } // end class PlusFlagTest

```

```
786 -786
+786 -786
```

[Figure 28.17](#) prefixes a space to the positive number with the `space flag`. This is useful for aligning positive and negative numbers with the same number of digits. Note that the value `-547` is not preceded by a space in the output because of its minus sign. [Figure 28.18](#) uses the `# flag` to prefix `0` to the octal value and `0x` to the hexadecimal value.

Figure 28.17. Using the space flag to print a space before non-negative values.

(This item is displayed on page 1340 in the print version)

```

(50)
(5.0e+01)
```

## 28.11. Printing with Argument Indices

An [argument index](#) is an optional decimal integer followed by a `$` sign that indicates the position of the argument in the argument list. For example, lines 2021 and 2425 in [Fig. 28.9](#) use argument index `"1$"` to indicate that all format specifiers use the first argument in the argument list. Argument indices enable programmers to reorder the output so that the arguments in the argument list are not necessarily in the order of their corresponding format specifiers. Argument indices also help avoid duplicating arguments. [Figure 28.22](#) demonstrates how to print arguments in the argument list in reverse order using the argument index.

Figure 28.22. Reordering output with argument indices.

```
1 // Fig. 28.22: ArgumentIndexTest
2 // Reordering output with argument indices.
3
4 public class ArgumentIndexTest
5 {
6 public static void main(String args[])
7 {
8 System.out.printf(
9 "Parameter list without reordering: %s %s %s %s\n",
10 "first", "second", "third", "fourth");
11 System.out.printf(
12 "Parameter list after reordering: %4$s %3$s %2$s %1$s\n",
13 "first", "second", "third", "fourth");
14 } // end main
15 } // end class ArgumentIndexTest
```

```
Parameter list without reordering: first second third fourth
Parameter list after reordering: fourth third second first
```

# 28.12. Printing Literals and Escape Sequences

Most literal characters to be printed in a `printf` statement can simply be included in the format string. However, there are several "problem" characters, such as the quotation mark (") that delimits the format string itself. Various control characters, such as newline and tab, must be represented by escape sequences. An escape sequence is represented by a backslash (\), followed by an escape character. [Figure 28.23](#) lists the escape sequences and the actions they cause.

Figure 28.23. Escape sequences.

(This item is displayed on page 1343 in the print version)

Escape sequence	Description
<code>\'</code> (single quote)	Output the single quote (') character.
<code>\"</code> (double quote)	Output the double quote (") character.
<code>\\</code> (backslash)	Output the backslash (\) character.
<code>\b</code> (backspace)	Move the cursor back one position on the current line.
<code>\f</code> (new page or form feed)	Move the cursor to the start of the next logical page.
<code>\n</code> (newline)	Move the cursor to the beginning of the next line.
<code>\r</code> (carriage return)	Move the cursor to the beginning of the current line.
<code>\t</code> (horizontal tab)	Move the cursor to the next horizontal tab position.

## Common Programming Error 28.4

*Attempting to print as literal data in a `printf` statement a double quote or backslash character without preceding that character with a backslash to form a proper escape sequence might result in a syntax error.*

## 28.13. Formatting Output with Class Formatter

So far, we have discussed displaying formatted output to the standard output stream. What should we do if we want to send formatted outputs to other output streams or devices, such as a `JTextArea` or a file? The solution relies on class `Formatter` (in package `java.util`), which provides the same formatting capabilities as `printf`. `Formatter` is a utility class that enables programmers to output formatted data to a specified destination, such as a file on disk. By default, a `Formatter` creates a string in memory. [Figure 28.24](#) demonstrates how to use a `Formatter` to build a formatted string, which is then displayed in a message dialog.

---

[Page 1343]

Figure 28.24. Formatting output with class `Formatter`.

```
1 // Fig. Fig. 28.24: FormatterTest.java
2 // Format string with class Formatter.
3 import java.util.Formatter;
4 import javax.swing.JOptionPane;
5
6 public class FormatterTest
7 {
8 public static void main(String args[])
9 {
10 // create Formatter and format output
11 Formatter formatter = new Formatter();
12 formatter.format("%d = %#o = %#X", 10, 10, 10);
13
14 // display output in JOptionPane
15 JOptionPane.showMessageDialog(null, formatter.toString());
16 } // end main
17 } // end class FormatterTest
```

Line 11 creates a `Formatter` object using the default constructor, so this object will build a string in memory. Other constructors are provided to allow you to specify the destination to which the formatted data should be output. For details, see [java.sun.com/j2se/5.0/docs/api/java/util/Formatter.html](http://java.sun.com/j2se/5.0/docs/api/java/util/Formatter.html).

---

[Page 1344]

Line 12 invokes method `format` to format the output. Like `printf`, method `format` takes a format string and an argument list. The difference is that `printf` sends the formatted output directly to the standard output

stream, while `format` sends the formatted output to the destination specified by its constructor (a string in memory in this program). Line 15 invokes the `Formatter`'s `toString` method to get the formatted data as a string, which is then displayed in a message dialog.

## String static Method format

Note that class `String` also provides a `static` convenience method named `format` that enables you to create a string in memory without the need to first create a `Formatter` object. Lines 1112 and line 15 in [Fig. 28.24](#) could have been replaced by

```
String s = String.format("%d = %#o = %#^x", 10, 10, 10);
JOptionPane.showMessageDialog(null, s);
```

[< PREV](#)[NEXT >](#)

## 28.14. Wrap-Up

This chapter summarized how to display formatted output with various format characters and flags. We displayed decimal numbers using format characters `d`, `o`, `x` and `X`. We displayed floating-point numbers using format characters `e`, `E`, `f`, `g` and `G`. We displayed date and time in various format using format characters `t` and `T` and their conversion suffix characters. You learned how to display output with field widths and precisions. We introduced the flags `+`, `-`, `space`, `#`, `0`, comma and `(` that are used together with the format characters to produce output. We also demonstrated how to format output with class `Formatter`. In the next chapter, we discuss the `String` class's methods for manipulating strings. We also introduce regular expressions and demonstrate how to validate user input with regular expressions.

## Summary

- Input and output are usually performed with streams, which are sequences of bytes. In input operations, the bytes flow from a device to main memory. In output operations, bytes flow from main memory to a device.
- Normally, the standard input stream is connected to the keyboard, and the standard output stream is connected to the computer screen.
- The `printf` format string describes the formats in which the output values appear. The format specifier consists of argument index, flags, field widths, precisions and conversion characters.
- Integers are printed with the conversion characters `d` for decimal integers, `o` for integers in octal form and `x` (or `X`) for integers in hexadecimal form. When the conversion character `x` is used, the output is displayed in uppercase letters.
- Floating-point values are printed with the conversion characters `e` (or `E`) for exponential notation, `f` for regular floating-point notation, and `g` (or `G`) for either `e` (or `E`) notation or `f` notation. When the `g` conversion specifier is indicated, the `e` conversion character is used if the value is less than  $10^3$  or greater than or equal to  $10^7$ ; otherwise, the `f` conversion character is used. When the conversion characters `E` and `G` are used, the output is displayed in uppercase letters.

- The conversion character `c` prints a character.
- The conversion character `s` (or `S`) prints a string of characters. When the conversion character `s` is used, the output is displayed in uppercase letters.
- The conversion character `t` (or `T`) followed by a conversion suffix character prints the date and time in various forms. When the conversion character `T` is used, the output is displayed in uppercase letters.
- Conversion character `t` (or `T`) requires the argument to be of type `long`, `Long`, `Calendar` or `Date`.
- Conversion character `b` (or `B`) outputs the string representation of a `boolean` or `Boolean`. These conversion characters also output `"true"` for non-`null` references and `"false"` for `null` references. When conversion character `B` is used, the output is displayed in uppercase letters.
- Conversion character `h` (or `H`) returns `null` for a `null` reference and a `String` representation of the hash code value (in base 16) of the object. Hash codes are used to store and retrieve objects in `Hashtables` and `HashMaps`. When conversion character `H` is used, the output is displayed in uppercase letters.
- The conversion character `n` prints the platform-specific line separator.
- The conversion character `%` is used to display a literal `%`.
- If the field width is larger than the object being printed, the object is right justified in the field by default.
- Field widths can be used with all conversion characters except the line-separator conversion.
- Precision used with floating-point conversion characters `e` and `f` indicates the number of digits that appear after the decimal point. Precision used with floating-point conversion character `g` indicates the number of significant digits to appear.

- Precision used with conversion character `s` indicates the number of characters to be printed.
- The field width and the precision can be combined by placing the field width, followed by a decimal point, followed by the precision between the percent sign and the conversion character.
- The `-` flag left justifies its argument in a field.
- The `+` flag prints a plus sign for positive values and a minus sign for negative values.
- The space flag prints a space preceding a positive value. The space flag and the `+` flag cannot be used together in an integral conversion character.
- The `#` flag prefixes `0` to octal values and `0x` to hexadecimal values.
- The `0` flag prints leading zeros for a value that does not occupy its entire field.
- The comma `,` flag uses the locale-specific thousands separator (i.e., `' , '` for U.S. locale) to display integer and floating-point numbers.
- The `(` flag encloses a negative number in parentheses.
- An argument index is an optional decimal integer followed by a `$` sign that indicates the position of the argument in the argument list.
- Argument indices enable programmers to reorder the output so that the arguments in the argument list are not necessarily in the order of their corresponding format specifiers. Argument indices also help avoid duplicating arguments.
- Class `Formatter` (in package `java.util`) provides the same formatting capabilities as `printf`. `Formatter` is a utility class that enables programmers to print formatted output to various destinations, including GUI components, files and other output streams.
- Class `Formatter`'s method `format` outputs formatted data to the destination specified by the `Formatter` constructor.
- The `static` method `format` of class `String` formats data and returns the formatted data as a `String`.

## Self-Review Exercises

28.1 Fill in the blanks in each of the following:

- a. All input and output is dealt with in the form of \_\_\_\_\_.
  - b. The \_\_\_\_\_ stream is normally connected to the keyboard.
  - c. The \_\_\_\_\_ stream is normally connected to the computer screen.
  - d. `System.out`'s \_\_\_\_\_ method can be used to format text that is displayed on the standard output.
  - e. The conversion character \_\_\_\_\_ may be used to output a decimal integer.
- 

[Page 1347]

- f. The conversion characters \_\_\_\_\_ and \_\_\_\_\_ are used to display integers in octal and hexadecimal form, respectively.
- g. The conversion character \_\_\_\_\_ is used to display a floating-point value in exponential notation.
- h. The conversion characters `e` and `f` are displayed with \_\_\_\_\_ digits of precision to the right of the decimal point if no precision is specified.
- i. The conversion characters \_\_\_\_\_ and \_\_\_\_\_ are used to print strings and characters, respectively.
- j. The conversion character \_\_\_\_\_ and conversion suffix character \_\_\_\_\_ are used to print time for the 24-hour clock as `hour:minute:second`.
- k. The \_\_\_\_\_ flag causes output to be left justified in a field.
- l. The \_\_\_\_\_ flag causes values to be displayed with either a plus sign or a minus sign.
- m. The argument index \_\_\_\_\_ corresponds to the second argument in the argument list.
- n. Class \_\_\_\_\_ has the same capability as `printf`, but allows programmers to print formatted output to various destinations besides the standard output stream.

28.2 Find the error in each of the following and explain how it can be corrected.

- a. The following statement should print the character `'c'`.

```
System.out.printf("%c\n", "c");
```

- b. The following statement should print `9.375%`.

```
System.out.printf("%.3f%", 9.375);
```

- c. The following statement should print the third argument in the argument list.

```
System.out.printf("%2$s\n", "Mon", "Tue", "Wed", "Thu", "Fri");
```

- d. `System.out.printf( "A string in quotes" );`  
e. `System.out.printf( %d %d, 12, 20 );`  
f. `System.out.printf( "%s\n", 'Richard' );`

### 28.3 Write a statement for each of the following:

- a. Print `1234` right justified in a 10 digit field.  
b. Print `123.456789` in exponential notation with a sign (+ or -) and 3 digits of precision.  
c. Print `100` in octal form preceded by 0.  
d. Given a `Calendar` object `calendar`, print a date formatted as month/day/year (each with two digits).  
e. Given a `Calendar` object `calendar`, print a time for the 24-hour clock as `hour:minute:second` (each with two digits) using argument index and conversion suffix characters for formatting time.  
f. Print `3.333333` with a sign (+ or -) in a field of 20 characters with a precision of 3.

## Answers to Self-Review Exercises

28.1 a) Streams. b) Standard input. c) Standard output. d) `printf`. e) `d`. f) `o`, `x` or `X`. g) `e` or `E`. h) `6`.  
i) `s` or `S`, `c` or `C`. j) `t`, `T`. k) `-` (minus). l) `+` (plus). m) `2$`. n) `Formatter`.

### 28.2

- a. Error: Conversion character `c` expects an argument of primitive type `char`.  
Correction: To print the character `'c'`, change `"c"` to `'c'`.
- b. Error: Trying to print the literal character `%` without using the format specifier `%%`.  
Correction: Use `%%` to print a literal `%` character.
- c. Error: Argument index does not start with 0, e.g., the first argument is `1$`.  
Correction: To print the third argument use `3$`.
- d. Error: Trying to print the literal character `"` without using the `\` escape sequence.  
Correction: Replace each quote in the inner set of quotes with `\`.
- 

[Page 1348]

- e. Error: The format string is not enclosed in double quotes.  
Correction: Enclose `%d %d` in double quotes.
- f. Error: The string to be printed is enclosed in single quotes.  
Correction: Use double quotes instead of single quotes to represent a string.

### 28.3

- a. `System.out.printf( "%10d\n", 1234 );`
- b. `System.out.printf( "%+.3e\n", 123.456789 );`
- c. `System.out.printf( "%#o\n", 100 );`
- d. `System.out.printf( "%tD\n", calendar );`
- e. `System.out.printf( "%1$tH:%1$tM:%1$tS\n", calendar );`
- f. `System.out.printf( "%+20.3f\n", 3.333333 );`

## Exercises

28.4 Write statement(s) for each of the following:

- Print integer 40000 right justified in a 15-digit field.
- Print 200 with and without a sign.
- Print 100 in hexadecimal form preceded by 0x.
- Print 1.234 with three digits of precision in a nine-digit field with preceding zeros.

28.5 Show what is printed by each of the following statements. If a statement is incorrect, indicate why.

- `System.out.printf( "%-10d\n", 10000 );`
- `System.out.printf( "%c\n", "This is a string" );`
- `System.out.printf( "%8.3f\n", 1024.987654 );`
- `System.out.printf( "%#o\n%#X\n", 17, 17 );`
- `System.out.printf( "% d\n%+d\n", 1000000, 1000000 );`
- `System.out.printf( "%10.2e\n", 444.93738 );`
- `System.out.printf( "%d\n", 10.987 );`

28.6 Find the error(s) in each of the following program segments. Show the corrected statement.

- `System.out.printf( "%s\n", 'Happy Birthday' );`
- `System.out.printf( "%c\n", 'Hello' );`
- `System.out.printf( "%c\n", "This is a string" );`
- The following statement should print "Bon Voyage" with the double quotes:

```
System.out.printf("%s", "Bon Voyage");
```

- The following statement should print "Today is Friday":

```
System.out.printf("Today is %s\n", "Monday", "Friday");
```

- `System.out.printf( 'Enter your name: ' );`

g. `System.out.printf( %f, 123.456 );`

h. The following statement should print the current time in the format `"hh:mm:ss"`:

```
Calendar dateTime = Calendar.getInstance();
System.out.printf("%1$tk:1$%t1:%1$tS\n", dateTime);
```

28.7 (*Printing Dates and Times*) Write a program that prints dates and times in the following forms:

```
GMT-05:00 04/30/04 09:55:09 AM
GMT-05:00 April 30 2004 09:55:09
2004-04-30 day-of-the-month:30
2004-04-30 day-of-the-year:121
Fri Apr 30 09:55:09 GMT-05:00 2004
```

---

[Page 1349]

[ *Note:* Depending on your location, you may get the time zone other than GMT-05:00.]

28.8 Write a program to test the results of printing the integer value `12345` and the floating-point value `1.2345` in various size fields.

28.9 (*Rounding Numbers*) Write a program that prints the value `100.453627` rounded to the nearest digit, tenth, hundredth, thousandth and ten thousandth.

28.10 Write a program that inputs a word from the keyboard and determines the length of the word. Print the word using twice the length as the field width.

28.11 (*Converting Fahrenheit Temperature to Celsius*) Write a program that converts integer Fahrenheit temperatures from `0` to `212` degrees to floating-point Celsius temperatures with three digits of precision. Use the formula

```
celsius = 5.0 / 9.0 * (fahrenheit - 32);
```

to perform the calculation. The output should be printed in two right-justified columns of 10 characters each, and the Celsius temperatures should be preceded by a sign for both positive and negative values.

28.12 Write a program to test all the escape sequences in [Fig. 28.23](#). For the escape sequences that move the cursor, print a character before and after the escape sequence so that it is clear where the cursor has moved.

28.13 Write a program that uses the conversion character `g` to output the value `9876.12345`. Print the value with precisions ranging from `1` to `9`.

# Chapter 29. Strings, Characters and Regular Expressions

*The chief defect of Henry King Was chewing little bits of string.*

Hilaire Belloc

*Vigorous writing is concise. A sentence should contain no unnecessary words, a paragraph no unnecessary sentences.*

William Strunk, Jr.

*I have made this letter longer than usual, because I lack the time to make it short.*

Blaise Pascal

## OBJECTIVES

In this chapter you will learn:

- To create and manipulate immutable character string objects of class `String`.
- To create and manipulates mutable character string objects of class `StringBuffer`.
- To create and manipulate objects of class `Character`.
- To use a `StringTokenizer` object to break a `String` object into tokens.
- To use regular expressions to validate `String` data entered into an application.

## 29.1. Introduction

This chapter introduces Java's string- and character-processing capabilities. The techniques discussed here are appropriate for validating program input, displaying information to users and other text-based manipulations. The techniques are also appropriate for developing text editors, word processors, page-layout software, computerized typesetting systems and other kinds of text-processing software. We have already presented several string-processing capabilities in earlier chapters. This chapter discusses in detail the capabilities of class `String`, class `StringBuffer` and class `Character` from the `java.lang` package and class `StringTokenizer` from the `java.util` package. These classes provide the foundation for string and character manipulation in Java.

The chapter also discusses regular expressions that provide applications with the capability to validate input. The functionality is located in the `String` class along with classes `Matcher` and `Pattern` located in the `java.util.regex` package.

## 29.2. Fundamentals of Characters and Strings

Characters are the fundamental building blocks of Java source programs. Every program is composed of a sequence of characters that when grouped together meaningfully are interpreted by the computer as a series of instructions used to accomplish a task. A program may contain [character literals](#). A character literal is an integer value represented as a character in single quotes. For example, `'z'` represents the integer value of `z`, and `'\n'` represents the integer value of newline. The value of a character literal is the integer value of the character in the [Unicode character set](#). [Appendix B](#) presents the integer equivalents of the characters in the ASCII character set, which is a subset of Unicode (discussed in [Appendix F](#)). For detailed information on Unicode, visit [www.unicode.org](http://www.unicode.org).

Recall from [Section 2.2](#) that a string is a sequence of characters treated as a single unit. A string may include letters, digits and various [special characters](#), such as `+`, `-`, `*`, `/` and `$`. A string is an object of class `String`. [String literals](#) (stored in memory as `String` objects) are written as a sequence of characters in double quotation marks, as in:

<code>"John Q. Doe"</code>	(a name)
<code>"9999 Main Street"</code>	(a street address)
<code>"Waltham, Massachusetts"</code>	(a city and state)
<code>"(201) 555-1212"</code>	(a telephone number)

A string may be assigned to a `String` reference. The declaration

```
String color = "blue";
```

initializes `String` reference `color` to refer to a `String` object that contains the string `"blue"`.

### Performance Tip 29.1

*Java treats all string literals with the same contents as a single `String` object that has many references to it. This conserves memory.*

## 29.3. Class `String`

Class `String` is used to represent strings in Java. The next several subsections cover many of class `String`'s capabilities.

### 29.3.1. `String` Constructors

Class `String` provides constructors for initializing `String` objects in a variety of ways. Four of the constructors are demonstrated in the `main` method of [Fig. 29.1](#).

Figure 29.1. `String` class constructors.

(This item is displayed on page 1353 in the print version)

```
1 // Fig. 29.1: StringConstructors.java
2 // String class constructors.
3
4 public class StringConstructors
5 {
6 public static void main(String args[])
7 {
8 char charArray[] = { 'b', 'i', 'r', 't', 'h', ' ', 'd', 'a', 'y' };
9 String s = new String("hello");
10
11 // use String constructors
12 String s1 = new String();
13 String s2 = new String(s);
14 String s3 = new String(charArray);
15 String s4 = new String(charArray, 6, 3);
16
17 System.out.printf(
18 "s1 = %s\ns2 = %s\ns3 = %s\ns4 = %s\n",
19 s1, s2, s3, s4); // display strings
20 } // end main
21 } // end class StringConstructors
```

```
s1 =
s2 = hello
s3 = birth day
s4 = day
```

Line 12 instantiates a new `String` object using class `String`'s no-argument constructor and assigns its

reference to `s1`. The new `String` object contains no characters (the `empty string`) and has a length of 0.

Line 13 instantiates a new `String` object using class `String`'s constructor that takes a `String` object as an argument and assigns its reference to `s2`. The new `String` object contains the same sequence of characters as the `String` object `s` that is passed as an argument to the constructor.

## Software Engineering Observation 29.1

*It is not necessary to copy an existing `String` object. `String` objects are **immutable** their character contents cannot be changed after they are created, because class `String` does not provide any methods that allow the contents of a `String` object to be modified.*

---

[Page 1353]

Line 14 instantiates a new `String` object and assigns its reference to `s3` using class `String`'s constructor that takes a `char` array as an argument. The new `String` object contains a copy of the characters in the array.

Line 15 instantiates a new `String` object and assigns its reference to `s4` using class `String`'s constructor that takes a `char` array and two integers as arguments. The second argument specifies the starting position (the offset) from which characters in the array are accessed. Remember that the first character is at position 0. The third argument specifies the number of characters (the count) to access in the array. The new `String` object contains a string formed from the accessed characters. If the offset or the count specified as an argument results in accessing an element outside the bounds of the character array, a `StringIndexOutOfBoundsException` is thrown. We discussed exceptions in detail in [Chapter 13](#).

## Common Programming Error 29.1

*Attempting to access a character that is outside the bounds of a string (i.e., an index less than 0 or an index greater than or equal to the string's length) results in a `StringIndexOutOfBoundsException`.*

### 29.3.2. `String` Methods `length`, `charAt` and `getChars`

`String` methods `length`, `charAt` and `getChars` return the length of a string, obtain the character at a specific location in a string and retrieve a set of characters from a string as a char array, respectively. The application in [Fig. 29.2](#) demonstrates each of these methods.

---

[Page 1354]

Figure 29.2. `String` class character-manipulation methods.

```

1 // Fig. 29.2: StringMiscellaneous.java
2 // This application demonstrates the length, charAt and getChars
3 // methods of the String class.
4
5 public class StringMiscellaneous
6 {
7 public static void main(String args[])
8 {
9 String s1 = "hello there";
10 char charArray[] = new char[5];
11
12 System.out.printf("s1: %s", s1);
13
14 // test length method
15 System.out.printf("\nLength of s1: %d", s1.length());
16
17 // loop through characters in s1 with charAt and display reversed
18 System.out.print("\nThe string reversed is: ");
19
20 for (int count = s1.length() - 1; count >= 0; count--)
21 System.out.printf("%s ", s1.charAt(count));
22
23 // copy characters from string into charArray
24 s1.getChars(0, 5, charArray, 0);
25 System.out.print("\nThe character array is: ");
26
27 for (char character : charArray)
28 System.out.print(character);
29
30 System.out.println();
31 } // end main
32 } // end class StringMiscellaneous

```

```

s1: hello there
Length of s1: 11
The string reversed is: e r e h t o l l e h
The character array is: hello

```

Line 15 uses `String` method `length` to determine the number of characters in string `s1`. Like arrays, strings always know their own length. However, unlike arrays, you cannot access a `String`'s length via a `length` field; instead you must call the `String`'s `length` method.

The `for` statement at lines 20-21 print the characters of the string `s1` in reverse order (and separated by spaces). `String` method `charAt` (line 21) returns the character at a specific position in the string. Method `charAt` receives an integer argument that is used as the index and returns the character at that position. Like arrays, the first element of a string is at position 0.

Line 24 uses `String` method `getChars` to copy the characters of a string into a character array. The first

argument is the starting index in the string from which characters are to be copied. The second argument is the index that is one past the last character to be copied from the string. The third argument is the character array into which the characters are to be copied. The last argument is the starting index where the copied characters are placed in the target character array. Next, line 28 prints the `char` array contents one character at a time.

### 29.3.3. Comparing Strings

[Chapter 7](#) discussed sorting and searching arrays. Frequently, the information being sorted or searched consists of strings that must be compared to place them into the proper order or to determine whether a string appears in an array (or other collection). Class `String` provides several methods for comparing strings; these are demonstrated in the next two examples.

To understand what it means for one string to be greater than or less than another string, consider the process of alphabetizing a series of last names. You would, no doubt, place "Jones" before "Smith" because the first letter of "Jones" comes before the first letter of "Smith" in the alphabet. But the alphabet is more than just a list of 26 letters; it is an ordered set of characters. Each letter occurs in a specific position within the set. Z is more than just a letter of the alphabet; it is specifically the twenty-sixth letter of the alphabet.

How does the computer know that one letter comes before another? All characters are represented in the computer as numeric codes (see [Appendix B](#)). When the computer compares two strings, it actually compares the numeric codes of the characters in the strings.

[Figure 29.3](#) demonstrates `String` methods `equals`, `equalsIgnoreCase`, `compareTo` and `regionMatches` and using the equality operator `==` to compare `String` objects.

Figure 29.3. `String` comparisons.

(This item is displayed on pages 1356 - 1357 in the print version)

```
1 // Fig. 29.3: StringCompare.java
2 // String methods equals, equalsIgnoreCase, compareTo and regionMatches.
3
4 public class StringCompare
5 {
6 public static void main(String args[])
7 {
8 String s1 = new String("hello"); // s1 is a copy of "hello"
9 String s2 = "goodbye";
10 String s3 = "Happy Birthday";
11 String s4 = "happy birthday";
12
13 System.out.printf(
14 "s1 = %s\ns2 = %s\ns3 = %s\ns4 = %s\n\n", s1, s2, s3, s4);
15
16 // test for equality
17 if (s1.equals("hello")) // true
18 System.out.println("s1 equals \"hello\"");
19 else
20 System.out.println("s1 does not equal \"hello\"");
21
22 // test for equality with ==
23 if (s1 == "hello") // false; they are not the same object
24 System.out.println("s1 is the same object as \"hello\"");
25 else
26 System.out.println("s1 is not the same object as \"hello\"");
27 }
28 }
```

```

28 // test for equality (ignore case)
29 if (s3.equalsIgnoreCase(s4)) // true
30 System.out.printf("%s equals %s with case ignored\n", s3, s4);
31 else
32 System.out.println("s3 does not equal s4");
33
34 // test compareTo
35 System.out.printf(
36 "\ns1.compareTo(s2) is %d", s1.compareTo(s2));
37 System.out.printf(
38 "\ns2.compareTo(s1) is %d", s2.compareTo(s1));
39 System.out.printf(
40 "\ns1.compareTo(s1) is %d", s1.compareTo(s1));
41 System.out.printf(
42 "\ns3.compareTo(s4) is %d", s3.compareTo(s4));
43 System.out.printf(
44 "\ns4.compareTo(s3) is %d\n\n", s4.compareTo(s3));
45
46 // test regionMatches (case sensitive)
47 if (s3.regionMatches(0, s4, 0, 5))
48 System.out.println("First 5 characters of s3 and s4 match");
49 else
50 System.out.println(
51 "First 5 characters of s3 and s4 do not match");
52
53 // test regionMatches (ignore case)
54 if (s3.regionMatches(true, 0, s4, 0, 5))
55 System.out.println("First 5 characters of s3 and s4 match");
56 else
57 System.out.println(
58 "First 5 characters of s3 and s4 do not match");
59 } // end main
60 } // end class StringCompare

```

```

s1 = hello
s2 = goodbye
s3 = Happy Birthday
s4 = happy birthday

s1 equals "hello"
s1 is not the same object as "hello"
Happy Birthday equals happy birthday with case ignored

s1.compareTo(s2) is 1
s2.compareTo(s1) is -1
s1.compareTo(s1) is 0
s3.compareTo(s4) is -32
s4.compareTo(s3) is 32

First 5 characters of s3 and s4 do not match
First 5 characters of s3 and s4 match

```

The condition at line 17 uses method `equals` to compare string `s1` and the string literal `"hello"` for equality. Method `equals` (a method of class `Object` overridden in `String`) tests any two objects for equality; the strings contained in the two objects are identical. The method returns `true` if the contents of the objects are equal, and `false` otherwise. The preceding condition is `TRUE` because string `s1` was initialized with the string literal `"hello"`. Method `equals` uses a [lexicographical comparison](#); it compares the integer Unicode values (see [Appendix F](#), Unicode, for more information) that represent each character in each string. Thus, if the string `"hello"` is compared with the string `"HELLO"`, the result is `false`, because the integer representation of a lowercase letter is different from that of the corresponding uppercase letter.

The condition at line 23 uses the equality operator `==` to compare string `s1` for equality with the string literal `"hello"`. Operator `==` has different functionality when it is used to compare references than when it is used to compare values of primitive types. When primitive-type values are compared with `==`, the result is `true` if both values are identical. When references are compared with `==`, the result is `true` if both references refer to the same object in memory. To compare the actual contents (or state information) of objects for equality, a method must be invoked. In the case of `Strings`, that method is `equals`. The preceding condition evaluates to `false` at line 23 because the reference `s1` was initialized with the statement

```
s1 = new String("hello");
```

---

[Page 1357]

which creates a new `String` object with a copy of string literal `"hello"` and assigns the new object to variable `s1`. If `s1` had been initialized with the statement

```
s1 = "hello";
```

which directly assigns the string literal `"hello"` to variable `s1`, the condition would be `TRUE`. Remember that Java treats all string literal objects with the same contents as one `String` object to which there can be many references. Thus, lines 8, 17 and 23 all refer to the same `String` object `"hello"` in memory.

## Common Programming Error 29.2

*Comparing references with `==` can lead to logic errors, because `==` compares the references to determine whether they refer to the same object, not whether two objects have the same contents. When two identical (but separate) objects are compared with `==`, the result will be `false`. When comparing objects to determine whether they have the same contents, use method `equals`.*

If you are sorting `Strings`, you may compare them for equality with method `equalsIgnoreCase`, which ignores whether the letters in each string are uppercase or lowercase when performing the comparison. Thus, the string `"hello"` and the string `"HELLO"` compare as equal. Line 29 uses `String` method `equalsIgnoreCase` to compare string `s3Happy Birthday` for equality with string `s4happy birthday`. The result of this comparison is `true` because the comparison ignores case sensitivity.

Lines 35-44 use method `compareTo` to compare strings. Method `compareTo` is declared in the `Comparable` interface and implemented in the `String` class. Line 36 compares string `s1` to string `s2`. Method `compareTo` returns 0 if the strings are equal, a negative number if the string that invokes `compareTo` is less than the string that is passed as an argument and a positive number if the string that invokes `compareTo` is greater

than the string that is passed as an argument. Method `compareTo` uses a lexicographical comparison it compares the numeric values of corresponding characters in each string. (For more information on the exact value returned by the `compareTo` method, see [java.sun.com/j2se/5.0/docs/api/java/lang/String.html](http://java.sun.com/j2se/5.0/docs/api/java/lang/String.html).)

---

[Page 1358]

The condition at line 47 uses `String` method `regionMatches` to compare portions of two strings for equality. The first argument is the starting index in the string that invokes the method. The second argument is a comparison string. The third argument is the starting index in the comparison string. The last argument is the number of characters to compare between the two strings. The method returns `TRUE` only if the specified number of characters are lexicographically equal.

Finally, the condition at line 54 uses a five-argument version of `String` method `regionMatches` to compare portions of two strings for equality. When the first argument is true, the method ignores the case of the characters being compared. The remaining arguments are identical to those described for the four-argument `regionMatches` method.

The second example in this section ([Fig. 29.4](#)) demonstrates `String` methods `startsWith` and `endsWith`. Method `main` creates array `strings` containing the strings "started", "starting", "ended" and "ending". The remainder of method `main` consists of three for statements that test the elements of the array to determine whether they start with or end with a particular set of characters.

Figure 29.4. `String` class `startsWith` and `endsWith` methods.

(This item is displayed on page 1359 in the print version)

```
1 // Fig. 29.4: StringStartEnd.java
2 // String methods startsWith and endsWith.
3
4 public class StringStartEnd
5 {
6 public static void main(String args[])
7 {
8 String strings[] = { "started", "starting", "ended", "ending" };
9
10 // test method startsWith
11 for (String string : strings)
12 {
13 if (string.startsWith("st"))
14 System.out.printf("\"%s\" starts with \"st\"\n", string);
15 } // end for
16
17 System.out.println();
18
19 // test method startsWith starting from position 2 of string
20 for (String string : strings)
21 {
22 if (string.startsWith("art", 2))
23 System.out.printf(
24 "\"%s\" starts with \"art\" at position 2\n", string);
25 } // end for
26
27 System.out.println();
28
29 // test method endsWith
30 for (String string : strings)
31 {
```

```

32 if (string.endsWith("ed"))
33 System.out.printf("\"%s\" ends with \"ed\\n\"", string);
34 } // end for
35 } // end main
36 } // end class StringStartEnd

```

```

"started" starts with "st"
"starting" starts with "st"

"started" starts with "art" at position 2
"starting" starts with "art" at position 2

"started" ends with "ed"
"ended" ends with "ed"

```

The first `for` statement (lines 1115) uses the version of method `startsWith` that takes a `String` argument. The condition in the `if` statement (line 13) determines whether each `String` in the array starts with the characters `"st"`. If so, the method returns `true` and the application prints that `String`. Otherwise, the method returns `false` and nothing happens.

The second `for` statement (lines 2025) uses the `startsWith` method that takes a `String` and an integer as arguments. The integer specifies the index at which the comparison should begin in the string. The condition in the `if` statement (line 22) determines whether each `String` in the array has the characters `"art"` beginning with the third character in each string. If so, the method returns `true` and the application prints the `String`.

The third `for` statement (lines 3034) uses method `endsWith`, which takes a `String` argument. The condition at line 32 determines whether each `String` in the array ends with the characters `"ed"`. If so, the method returns `true` and the application prints the `String`.

### 29.3.4. Locating Characters and Substrings in Strings

Often it is useful to search for a character or set of characters in a string. For example, if you are creating your own word processor, you might want to provide a capability for searching through documents. [Figure 29.5](#) demonstrates the many versions of `String` methods `indexOf` and `lastIndexOf` that search for a specified character or substring in a string. All the searches in this example are performed on the string `letters` (initialized with `"abcdefghijklmabcdefghijklm"`) in method `main`. Lines 1116 use method `indexOf` to locate the first occurrence of a character in a string. If method `indexOf` finds the character, it returns the character's index in the string; otherwise, `indexOf` returns `1`. There are two versions of `indexOf` that search for characters in a string. The expression in line 12 uses the version of method `indexOf` that takes an integer representation of the character to find. The expression at line 14 uses another version of method `indexOf`, which takes two integer arguments: the character and the starting index at which the search of the string should begin.

Figure 29.5. `String` class searching methods.

```
1 // Fig. 29.5: StringIndexMethods.java
2 // String searching methods indexOf and lastIndexOf.
3
4 public class StringIndexMethods
5 {
6 public static void main(String args[])
7 {
8 String letters = "abcdefghijklmabcdefghijklm";
9
10 // test indexOf to locate a character in a string
11 System.out.printf(
12 "'c' is located at index %d\n", letters.indexOf('c'));
13 System.out.printf(
14 "'a' is located at index %d\n", letters.indexOf('a', 1));
15 System.out.printf(
16 "'$' is located at index %d\n\n", letters.indexOf('$'));
17
18 // test lastIndexOf to find a character in a string
19 System.out.printf("Last 'c' is located at index %d\n",
20 letters.lastIndexOf('c'));
21 System.out.printf("Last 'a' is located at index %d\n",
22 letters.lastIndexOf('a', 25));
23 System.out.printf("Last '$' is located at index %d\n\n",
24 letters.lastIndexOf('$'));
25
26 // test indexOf to locate a substring in a string
27 System.out.printf("\"def\" is located at index %d\n",
28 letters.indexOf("def"));
29 System.out.printf("\"def\" is located at index %d\n",
30 letters.indexOf("def", 7));
31 System.out.printf("\"hello\" is located at index %d\n\n",
32 letters.indexOf("hello"));
33
34 // test lastIndexOf to find a substring in a string
35 System.out.printf("Last \"def\" is located at index %d\n",
36 letters.lastIndexOf("def"));
37 System.out.printf("Last \"def\" is located at index %d\n",
38 letters.lastIndexOf("def", 25));
39 System.out.printf("Last \"hello\" is located at index %d\n",
40 letters.lastIndexOf("hello"));
41 } // end main
42 } // end class StringIndexMethods
```

```
'c' is located at index 2
'a' is located at index 13
'$' is located at index -1

Last 'c' is located at index 15
Last 'a' is located at index 13
Last '$' is located at index -1

"def" is located at index 3
"def" is located at index 16
"hello" is located at index -1

Last "def" is located at index 16
Last "def" is located at index 16
Last "hello" is located at index -1
```

The statements at lines 1924 use method `lastIndexOf` to locate the last occurrence of a character in a string. Method `lastIndexOf` performs the search from the end of the string toward the beginning of the string. If method `lastIndexOf` finds the character, it returns the index of the character in the string; otherwise, `lastIndexOf` returns -1. There are two versions of `lastIndexOf` that search for characters in a string. The expression at line 20 uses the version of method `lastIndexOf` that takes the integer representation of the character. The expression at line 22 uses the version of method `lastIndexOf` that takes two integer arguments: the integer representation of the character and the index from which to begin searching backward.

---

[Page 1360]

---

[Page 1361]

Lines 2740 demonstrate versions of methods `indexOf` and `lastIndexOf` that each take a `String` as the first argument. These versions of the methods perform identically to those described earlier except that they search for sequences of characters (or substrings) that are specified by their `String` arguments. If the substring is found, these methods return the index in the string of the first character in the substring.

### 29.3.5. Extracting Substrings from Strings

Class `String` provides two `substring` methods to enable a new `String` object to be created by copying part of an existing `String` object. Each method returns a new `String` object. Both methods are demonstrated in [Fig. 29.6](#).

Figure 29.6. `String` class `substring` methods.

```

1 // Fig. 29.6: SubString.java
2 // String class substring methods.
3
4 public class SubString
5 {
6 public static void main(String args[])
7 {
8 String letters = abcdefghijklmabcdefgghijklm";
9
10 // test substring methods
11 System.out.printf("Substring from index 20 to end is \"%s\"\\n",
12 letters.substring(20));
13 System.out.printf("%s \"%s\"\\n",
14 "Substring from index 3 up to, but not including 6 is",
15 letters.substring(3, 6));
16 } // end main
17 } // end class SubString

```

```

Substring from index 20 to end is "hijklm"
Substring from index 3 up to, but not including 6 is "def"

```

[Page 1362]

The expression `letters.substring( 20 )` at line 12 uses the `substring` method that takes one integer argument. The argument specifies the starting index in the original string `letters` from which characters are to be copied. The substring returned contains a copy of the characters from the starting index to the end of the string. Specifying an index outside the bounds of the string causes a **`StringIndexOutOfBoundsException`**.

The expression `letters.substring( 3, 6 )` at line 15 uses the `substring` method that takes two integer arguments. The first argument specifies the starting index from which characters are copied in the original string. The second argument specifies the index one beyond the last character to be copied (i.e., copy up to, but not including, that index in the string). The substring returned contains a copy of the specified characters from the original string. Specifying an index outside the bounds of the string causes a **`StringIndexOutOfBoundsException`**.

### 29.3.6. Concatenating Strings

`String` method `concat` (Fig. 29.7) concatenates two `String` objects and returns a new `String` object containing the characters from both original strings. The expression `s1.concat( s2 )` at line 13 forms a string by appending the characters in string `s2` to the characters in string `s1`. The original `Strings` to which `s1` and `s2` refer are not modified.

Figure 29.7. **`String`** method `concat`.

```

1 // Fig. 29.7: StringConcatenation.java
2 // String concat method.
3
4 public class StringConcatenation
5 {
6 public static void main(String args[])
7 {
8 String s1 = new String("Happy ");
9 String s2 = new String("Birthday");
10
11 System.out.printf("s1 = %s\ns2 = %s\n\n", s1, s2);
12 System.out.printf(
13 "Result of s1.concat(s2) = %s\n", s1.concat(s2));
14 System.out.printf("s1 after concatenation = %s\n", s1);
15 } // end main
16 } // end class StringConcatenation

```

```

s1 = Happy
s2 = Birthday

Result of s1.concat(s2) = Happy Birthday
s1 after concatenation = Happy

```

### 29.3.7. Miscellaneous String Methods

Class `String` provides several methods that return modified copies of strings or that return character arrays. These methods are demonstrated in the application in [Fig. 29.8](#).

Figure 29.8. `String` methods `replace`, `toLowerCase`, `toUpperCase`, `trim` and `toCharArray`.

(This item is displayed on page 1363 in the print version)

```

1 // Fig. 29.8: StringMiscellaneous2.java
2 // String methods replace, toLowerCase, toUpperCase, trim and toCharArray.
3
4 public class StringMiscellaneous2
5 {
6 public static void main(String args[])
7 {
8 String s1 = new String("hello");
9 String s2 = new String("GOODBYE");
10 String s3 = new String(" spaces ");
11
12 System.out.printf("s1 = %s\ns2 = %s\ns3 = %s\n\n", s1, s2, s3);
13
14 // test method replace
15 System.out.printf(
16 "Replace 'l' with 'L' in s1: %s\n\n", s1.replace('l', 'L'));
17
18 // test toLowerCase and toUpperCase
19 System.out.printf("s1.toUpperCase() = %s\n", s1.toUpperCase());
20 System.out.printf("s2.toLowerCase() = %s\n\n", s2.toLowerCase());
21
22 // test trim method
23 System.out.printf("s3 after trim = \"%s\"\n\n", s3.trim());
24
25 // test toCharArray method
26 char charArray[] = s1.toCharArray();
27 System.out.print("s1 as a character array = ");
28
29 for (char character : charArray)
30 System.out.print(character);
31
32 System.out.println();
33 } // end main
34 } // end class StringMiscellaneous2

```

```

s1 = hello
s2 = GOODBYE
s3 = spaces

```

```

Replace 'l' with 'L' in s1: heLLo

```

```

s1.toUpperCase() = HELLO
s2.toLowerCase() = goodbye

```

```

s3 after trim = "spaces"

```

```

s1 as a character array = hello

```

Line 16 uses `String` method `replace` to return a new `String` object in which every occurrence in string `s1` of character `'l'` (lowercase el) is replaced with character `'L'`. Method `replace` leaves the original string unchanged. If there are no occurrences of the first argument in the string, method `replace` returns the

original string.

---

[Page 1363]

---

[Page 1364]

Line 19 uses `String` method `toUpperCase` to generate a new `String` object with uppercase letters where corresponding lowercase letters exist in `s1`. The method returns a new `String` object containing the converted string and leaves the original string unchanged. If there are no characters to convert, method `toUpperCase` returns the original string.

Line 20 uses `String` method `toLowerCase` to return a new `String` object with lowercase letters where corresponding uppercase letters exist in `s2`. The original string remains unchanged. If there are no characters in the original string to convert, `toLowerCase` returns the original string.

Line 23 uses `String` method `Trim` to generate a new `String` object that removes all whitespace characters that appear at the beginning or end of the string on which `trim` operates. The method returns a new `String` object containing the `string` without leading or trailing white space. The original string remains unchanged.

Line 26 uses `String` method `toCharArray` to create a new character array containing a copy of the characters in string `s1`. Lines 29-30 output each char in the array.

### 29.3.8. `String` Method `valueOf`

As we have seen, every object in Java has a `toString` method that enables a program to obtain the object's string representation. Unfortunately, this technique cannot be used with primitive types because they do not have methods. Class `String` provides `static` methods that take an argument of any type and convert the argument to a `String` object. [Figure 29.9](#) demonstrates the `String` class `valueOf` methods.

Figure 29.9. `String` class `valueOf` methods.

(This item is displayed on page 1365 in the print version)

```
1 // Fig. 29.9: StringValueOf.java
2 // String valueOf methods.
3
4 public class StringValueOf
5 {
6 public static void main(String args[])
7 {
8 char charArray[] = { 'a', 'b', 'c', 'd', 'e', 'f' };
9 boolean booleanValue = true;
10 char characterValue = 'Z';
11 int integerValue = 7;
12 long longValue = 1000000000000L; // L suffix indicates long
13 float floatValue = 2.5f; // f indicates that 2.5 is a float
14 double doubleValue = 33.333; // no suffix, double is default
15 Object objectRef = "hello"; // assign string to an Object reference
16
17 System.out.printf(
18 "char array = %s\n", String.valueOf(charArray));
19 System.out.printf("part of char array = %s\n",
20 String.valueOf(charArray, 3, 3));
21 System.out.printf(
22 "boolean = %s\n", String.valueOf(booleanValue));
23 System.out.printf(
```

```

24 "char = %s\n", String.valueOf(characterValue));
25 System.out.printf("int = %s\n", String.valueOf(integerValue));
26 System.out.printf("long = %s\n", String.valueOf(longValue));
27 System.out.printf("float = %s\n", String.valueOf(floatValue));
28 System.out.printf(
29 "double = %s\n", String.valueOf(doubleValue));
30 System.out.printf("Object = %s", String.valueOf(objectRef));
31 } // end main
32 } // end class StringValueOf

```

```

char array = abcdef
part of char array = def
boolean = true
char = Z
int = 7
long = 100000000000
float = 2.5
double = 33.333
Object = hello

```

The expression `String.valueOf( charArray )` at line 18 uses the character array `charArray` to create a new `String` object. The expression `String.valueOf( charArray, 3, 3 )` at line 20 uses a portion of the character array `charArray` to create a new `String` object. The second argument specifies the starting index from which the characters are used. The third argument specifies the number of characters to be used.

There are seven other versions of method `valueOf`, which take arguments of type `boolean`, `char`, `int`, `long`, `float`, `double` and `Object`, respectively. These are demonstrated in lines 2130. Note that the version of `valueOf` that takes an `Object` as an argument can do so because all `Objects` can be converted to `Strings` with method `toString`.

[*Note:* Lines 1314 use literal values `10000000L` and `2.5f` as the initial values of long variable `longValue` and `float` variable `floatValue`, respectively. By default, Java treats integer literals as type `int` and floating-point literals as type `double`. Appending the letter `L` to the literal `10000000` and appending letter `f` to the literal `2.5` indicates to the compiler that `10000000` should be treated as a `long` and that `2.5` should be treated as a `float`. An uppercase `L` or lowercase `l` can be used to denote a variable of type `long` and an uppercase `F` or lowercase `f` can be used to denote a variable of type `float`.]

## 29.4. Class `StringBuffer`

Once a `String` object is created, its contents can never change. We now discuss the features of class `StringBuffer` for creating and manipulating dynamic string information—that is, modifiable strings. Every `StringBuffer` is capable of storing a number of characters specified by its capacity. If the capacity of a `StringBuffer` is exceeded, the capacity is automatically expanded to accommodate the additional characters. Class `StringBuffer` is also used to implement operators `+` and `+=` for `String` concatenation.

### Performance Tip 29.2

*Java can perform certain optimizations involving `String` objects (such as sharing one `String` object among multiple references) because it knows these objects will not change. `Strings` (not `StringBuffers`) should be used if the data will not change.*

### Performance Tip 29.3

*In programs that frequently perform string concatenation, or other string modifications, it is more efficient to implement the modifications with class `StringBuffer` (covered in [Section 29.4.1](#)).*

### 29.4.1. `StringBuffer` Constructors

Class `StringBuffer` provides four constructors. Three of these constructors are demonstrated in [Fig. 29.10](#). Line 8 uses the no-argument `StringBuffer` constructor to create a `StringBuffer` with no characters in it and an initial capacity of 16 characters (the default for a `StringBuffer`). Line 9 uses the `StringBuffer` constructor that takes an integer argument to create a `StringBuffer` with no characters in it and the initial capacity specified by the integer argument (i.e., 10). Line 10 uses the `StringBuffer` constructor that takes a `String` argument (in this case, a string literal) to create a `StringBuffer` containing the characters in the `String` argument. The initial capacity is the number of characters in the `String` argument plus 16.

Figure 29.10. `StringBuffer` class constructors.

```

1 // Fig. 29.10: StringBufferConstructors.java
2 // StringBuffer constructors.
3
4 public class StringBufferConstructors
5 {
6 public static void main(String args[])
7 {
8 StringBuffer buffer1 = new StringBuffer();
9 StringBuffer buffer2 = new StringBuffer(10);
10 StringBuffer buffer3 = new StringBuffer("hello");
11
12 System.out.printf("buffer1 = \"%s\"\n", buffer1.toString());
13 System.out.printf("buffer2 = \"%s\"\n", buffer2.toString());
14 System.out.printf("buffer3 = \"%s\"\n", buffer3.toString());
15 } // end main
16 } // end class StringBufferConstructors

```

```

buffer1 = ""
buffer2 = ""
buffer3 = "hello"

```

The statements on lines 12-14 use `StringBuffer` method `toString` to output the `StringBuffer` with the `printf` method. In [Section 29.4.4](#), we discuss how Java uses `StringBuffer` objects to implement the `+` and `+=` operators for string concatenation.

## 29.4.2. `StringBuffer` Methods `length`, `capacity`, `setLength` and `ensureCapacity`

Class `StringBuffer` provides methods `length` and `capacity` to return the number of characters currently in a `StringBuffer` and the number of characters that can be stored in a `StringBuffer` without allocating more memory, respectively. Method `ensureCapacity` guarantees that a `StringBuffer` has at least the specified capacity. Method `setLength` increases or decreases the length of a `StringBuffer`. The application in [Fig. 29.11](#) demonstrates these methods.

Figure 29.11. `StringBuffer` methods `length` and `capacity`.

(This item is displayed on page 1367 in the print version)

```

1 // Fig. 29.11: StringBufferCapLen.java
2 // StringBuffer length, setLength, capacity and ensureCapacity methods.
3
4 public class StringBufferCapLen
5 {
6 public static void main(String args[])
7 {
8 StringBuffer buffer = new StringBuffer("Hello, how are you?");
9
10 System.out.printf("buffer = %s\nlength = %d\ncapacity = %d\n\n",
11 buffer.toString(), buffer.length(), buffer.capacity());
12
13 buffer.ensureCapacity(75);
14 System.out.printf("New capacity = %d\n\n", buffer.capacity());
15
16 buffer.setLength(10);
17 System.out.printf("New length = %d\nbuf = %s\n",
18 buffer.length(), buffer.toString());
19 } // end main
20 } // end class StringBufferCapLen

```

```

buffer = Hello, how are you?
length = 19
capacity = 35

New capacity = 75

New length = 10
buf = Hello, how

```

The application contains one `StringBuffer` called `buffer`. Line 8 uses the `StringBuffer` constructor that takes a `String` argument to initialize the `StringBuffer` with "Hello, how are you?". Lines 10-11 print the contents, length and capacity of the `StringBuffer`. Note in the output window that the capacity of the `StringBuffer` is initially 35. Recall that the `StringBuffer` constructor that takes a `String` argument initializes the capacity to the length of the string passed as an argument plus 16.

Line 13 uses method `ensureCapacity` to expand the capacity of the `StringBuffer` to a minimum of 75 characters. Actually, if the original capacity is less than the argument, the method ensures a capacity that is the greater of the number specified as an argument and twice the original capacity plus 2. The `StringBuffer`'s current capacity remains unchanged if it is more than the specified capacity.

## Performance Tip 29.4

*Dynamically increasing the capacity of a `StringBuffer` can take a relatively long time. Executing a large number of these operations can degrade the performance of an application. If a `StringBuffer` is going to increase greatly in size, possibly multiple times, setting its capacity high at the beginning will increase performance.*

Line 16 uses method `setLength` to set the length of the `StringBuffer` to 10. If the specified length is less than the current number of characters in the `StringBuffer`, the buffer is truncated to the specified length (i.e., the characters in the `StringBuffer` after the specified length are discarded). If the specified length is greater than the number of characters currently in the `StringBuffer`, null characters (characters with the numeric representation 0) are appended to the `StringBuffer` until the total number of characters in the `StringBuffer` is equal to the specified length. See [Section 14.7.1](#) for more details.

### 29.4.3. `StringBuffer` Methods `charAt`, `setCharAt`, `getChars` and `reverse`

Class `StringBuffer` provides methods `charAt`, `setCharAt`, `getChars` and `reverse` to manipulate the characters in a `StringBuffer`. Each of these methods is demonstrated in [Fig. 29.12](#).

Figure 29.12. `StringBuffer` class character-manipulation methods.

```
1 // Fig. 29.12: StringBufferChars.java
2 // StringBuffer methods charAt, setCharAt, getChars and reverse.
3
4 public class StringBufferChars
5 {
6 public static void main(String args[])
7 {
8 StringBuffer buffer = new StringBuffer("hello there");
9
10 System.out.printf("buffer = %s\n", buffer.toString());
11 System.out.printf("Character at 0: %s\nCharacter at 4: %s\n\n",
12 buffer.charAt(0), buffer.charAt(4));
13
14 char charArray[] = new char[buffer.length()];
15 buffer.getChars(0, buffer.length(), charArray, 0);
16 System.out.print("The characters are: ");
17
18 for (char character : charArray)
19 System.out.print(character);
20
21 buffer.setCharAt(0, 'H');
22 buffer.setCharAt(6, 'T');
23 System.out.printf("\n\nbuf = %s", buffer.toString());
24
25 buffer.reverse();
26 System.out.printf("\n\nbuf = %s\n", buffer.toString());
27 } // end main
28 } // end class StringBufferChars
```

```
buffer = hello there
Character at 0: h
Character at 4: o

The characters are: hello there

buf = Hello There

buf = erehT olleH
```

[Page 1369]

Method `charAt` (line 12) takes an integer argument and returns the character in the `StringBuffer` at that index. Method `getChars` (line 15) copies characters from a `StringBuffer` into the character array passed as an argument. This method takes four arguments—the starting index from which characters should be copied in the `StringBuffer`, the index one past the last character to be copied from the `StringBuffer`, the character array into which the characters are to be copied and the starting location in the character array where the first character should be placed. Method `setCharAt` (lines 21 and 22) takes an integer and a character argument and sets the character at the specified position in the `StringBuffer` to the character argument. Method `reverse` (line 25) *reverses* the contents of the `StringBuffer`.

### Common Programming Error 29.3

*Attempting to access a character that is outside the bounds of a `StringBuffer` (i.e., with an index less than 0 or greater than or equal to the `StringBuffer`'s length) results in a `StringIndexOutOfBoundsException`.*

#### 29.4.4. `StringBuffer` append Methods

Class `StringBuffer` provides overloaded `append` methods to allow values of various types to be appended to the end of a `StringBuffer`. Versions are provided for each of the primitive types and for character arrays, `Strings`, `Objects`, `StringBuffers` and `CharSequences`. (Remember that method `toString` produces a string representation of any `Object`.) Each of the methods takes its argument, converts it to a `string` and appends it to the `StringBuffer`. The `append` methods are demonstrated in [Fig. 29.13](#).

Figure 29.13. `StringBuffer` class `append` methods.

(This item is displayed on pages 1370 - 1371 in the print version)

```
1 // Fig. 29.13: StringBufferAppend.java
2 // StringBuffer append methods.
3
4 public class StringBufferAppend
5 {
```

```

6 public static void main(String args[])
7 {
8 Object objectRef = "hello";
9 String string = "goodbye";
10 char charArray[] = { 'a', 'b', 'c', 'd', 'e', 'f' };
11 boolean booleanValue = true;
12 char characterValue = 'Z';
13 int integerValue = 7;
14 long longValue = 10000000000L;
15 float floatValue = 2.5f; // f suffix indicates 2.5 is a float
16 double doubleValue = 33.333;
17
18 StringBuffer lastBuffer = new StringBuffer("last StringBuffer");
19 StringBuffer buffer = new StringBuffer();
20
21 buffer.append(objectRef);
22 buffer.append("\n"); // each of these contains new line
23 buffer.append(string);
24 buffer.append("\n");
25 buffer.append(charArray);
26 buffer.append("\n");
27 buffer.append(charArray, 0, 3);
28 buffer.append("\n");
29 buffer.append(booleanValue);
30 buffer.append("\n");
31 buffer.append(characterValue);
32 buffer.append("\n");
33 buffer.append(integerValue);
34 buffer.append("\n");
35 buffer.append(longValue);
36 buffer.append("\n");
37 buffer.append(floatValue);
38 buffer.append("\n");
39 buffer.append(doubleValue);
40 buffer.append("\n");
41 buffer.append(lastBuffer
42
43 System.out.printf("buffer contains %s\n", buffer.toString());
44 } // end main
45 } // end StringBufferAppend

```

```

buffer contains hello
goodbye
abcdef
abc
true
Z
7
100000000000
2.5
33.333
last StringBuffer

```

Actually, `StringBuffers` and the append methods are used by the compiler to implement the `+` and `+=` operators for `String` concatenation. For example, assuming the declarations

```
String string1 = "hello";
String string2 = "BC";
int value = 22;
```

the statement

```
String s = string1 + string2 + value;
```

concatenates `"hello"`, `"BC"` and `22`. The concatenation is performed as follows:

```
new StringBuffer().append("hello").append("BC").append(
22).toString();
```

First, Java creates an empty `StringBuffer`, then appends to the `StringBuffer` the string `"hello"`, the string `"BC"` and the integer `22`. Next, `StringBuffer`'s method `toString` converts the `StringBuffer` to a `String` object to be assigned to `String s`. The statement

```
s += " !";
```

is performed as follows:

```
s = new StringBuffer().append(s).append(" !").toString();
```

---

[Page 1370]

First, Java creates an empty `StringBuffer`, then appends to the `StringBuffer` the current contents of `s` followed by `" !"`. Next, `StringBuffer`'s method `toString` converts the `StringBuffer` to a string representation and the result is assigned to `s`.

---

[Page 1371]

## 29.4.5. `StringBuffer` Insertion and Deletion Methods

Class `StringBuffer` provides overloaded `insert` methods to allow values of various types to be inserted at any position in a `StringBuffer`. Versions are provided for each of the primitive types and for character arrays, `Strings`, `Objects` and `CharSequences`. Each of the methods takes its second argument, converts it to a string and inserts it immediately preceding the index specified by the first argument. The index specified by the first argument must be greater than or equal to `0` and less than the length of the `StringBuffer` otherwise, a `StringIndexOutOfBoundsException` occurs. Class `StringBuffer` also provides methods `delete` and `deleteCharAt` for deleting characters at any position in a `StringBuffer`. Method `delete` takes two arguments the starting index and the index one past the end of the characters to delete. All

characters beginning at the starting index up to but not including the ending index are deleted. Method `deleteCharAt` takes one argument the index of the character to delete. Invalid indices cause both methods to throw a `String-IndexOutOfBoundsException`. Methods `insert`, `delete` and `deleteCharAt` are demonstrated in [Fig. 29.14](#).

Figure 29.14. `StringBuffer` methods `insert` and `delete`.

(This item is displayed on pages 1371 - 1372 in the print version)

```
1 // Fig. 29.14: StringBufferInsert.java
2 // StringBuffer methods insert, delete and deleteCharAt.
3
4 public class StringBufferInsert
5 {
6 public static void main(String args[])
7 {
8 Object objectRef = "hello";
9 String string = "goodbye";
10 char charArray[] = { 'a', 'b', 'c', 'd', 'e', 'f' };
11 boolean booleanValue = true;
12 char characterValue = 'K';
13 int integerValue = 7;
14 long longValue = 10000000;
15 float floatValue = 2.5f; // f suffix indicates that 2.5 is a float
16 double doubleValue = 33.333;
17
18 StringBuffer buffer = new StringBuffer();
19
20 buffer.insert(0, objectRef);
21 buffer.insert(0, " "); // each of these contains two spaces
22 buffer.insert(0, string);
23 buffer.insert(0, " ");
24 buffer.insert(0, charArray);
25 buffer.insert(0, " ");
26 buffer.insert(0, charArray, 3, 3);
27 buffer.insert(0, " ");
28 buffer.insert(0, booleanValue);
29 buffer.insert(0, " ");
30 buffer.insert(0, characterValue);
31 buffer.insert(0, " ");
32 buffer.insert(0, integerValue);
33 buffer.insert(0, " ");
34 buffer.insert(0, longValue);
35 buffer.insert(0, " ");
36 buffer.insert(0, floatValue);
37 buffer.insert(0, " ");
38 buffer.insert(0, doubleValue);
39
40 System.out.printf(
41 "buffer after inserts:\n%s\n\n", buffer.toString());
42
43 buffer.deleteCharAt(10); // delete 5 in 2.5
44 buffer.delete(2, 6); // delete .333 in 33.333
45
46 System.out.printf(
47 "buffer after deletes:\n%s\n", buffer.toString());
48 } // end main
49 } // end class StringBufferInsert
```

```
buffer after inserts:
33.333 2.5 10000000 7 K true def abcdef goodbye hello

buffer after deletes:
33 2. 10000000 7 K true def abcdef goodbye hello
```

## 29.5. Class Character

Recall from [Chapter 17](#) that Java provides eight type-wrapper classes `Boolean`, `Character`, `Double`, `Float`, `Byte`, `Short`, `Integer` and `Long` that enable primitive-type values to be treated as objects. In this section, we present class `Character` the type-wrapper class for primitive type `char`.

Most `Character` methods are `static` methods designed to be convenience methods for processing individual `char` values. These methods take at least a character argument and perform either a test or a manipulation of the character. Class `Character` also contains a constructor that receives a `char` argument to initialize a `Character` object. Most of the methods of class `Character` are presented in the next three examples. For more information on class `Character` (and all the type-wrapper classes), see the `java.lang` package in the Java API documentation.

[Figure 29.15](#) demonstrates some `static` methods that test characters to determine whether they are a specific character type and the `static` methods that perform case conversions on characters. You can enter any character and apply the methods to the character.

Figure 29.15. `Character` class `static` methods for testing characters and converting character case.

(This item is displayed on pages 1373 - 1374 in the print version)

```
1 // Fig. 29.15: StaticCharMethods.java
2 // Static Character testing methods and case conversion methods.
3 import java.util.Scanner;
4
5 public class StaticCharMethods
6 {
7 public static void main(String args[])
8 {
9 Scanner scanner = new Scanner(System.in); // create scanner
10 System.out.println("Enter a character and press Enter");
11 String input = scanner.next();
12 char c = input.charAt(0); // get input character
13
14 // display character info
15 System.out.printf("is defined: %b\n", Character.isDefined(c));
16 System.out.printf("is digit: %b\n", Character.isDigit(c));
17 System.out.printf("is first character in a Java identifier: %b\n",
18 Character.isJavaIdentifierStart(c));
19 System.out.printf("is part of a Java identifier: %b\n",
20 Character.isJavaIdentifierPart(c));
21 System.out.printf("is letter: %b\n", Character.isLetter(c));
22 System.out.printf(
23 "is letter or digit: %b\n", Character.isLetterOrDigit(c));
24 System.out.printf(
25 "is lower case: %b\n", Character.isLowerCase(c));
26 System.out.printf(
27 "is upper case: %b\n", Character.isUpperCase(c));
```

```
28 System.out.printf(
29 "to upper case: %s\n", Character.toUpperCase(c));
30 System.out.printf(
31 "to lower case: %s\n", Character.toLowerCase(c));
32 } // end main
33 } // end class StaticCharMethods
```

```
Enter a character and press Enter
A
is defined: true
is digit: false
is first character in a Java identifier: true
is part of a Java identifier: true
is letter: true
is letter or digit: true
is lower case: false
is upper case: true
to upper case: A
to lower case: a
```

```
Enter a character and press Enter
8
is defined: true
is digit: true
is first character in a Java identifier: false
is part of a Java identifier: true
is letter: false
is letter or digit: true
is lower case: false
is upper case: false
to upper case: 8
to lower case: 8
```

```
Enter a character and press Enter
$
is defined: true
is digit: false
is first character in a Java identifier: true
is part of a Java identifier: true
is letter: false
is letter or digit: false
is lower case: false
is upper case: false
to upper case: $
to lower case: $
```

Line 15 uses `Character` method `isDefined` to determine whether character `c` is defined in the Unicode character set. If so, the method returns `true`, and otherwise, it returns `false`. Line 16 uses `Character` method `isDigit` to determine whether character `c` is a defined Unicode digit. If so, the method returns `True`, and otherwise, it returns `false`.

Line 18 uses `Character` method `isJavaIdentifierStart` to determine whether `c` is a character that can be the first character of an identifier in Java that is, a letter, an underscore (`_`) or a dollar sign (`$`). If so, the method returns `True`, and otherwise, it returns `false`. Line 20 uses `Character` method `isJavaIdentifierPart` to determine whether character `c` is a character that can be used in an identifier in Java that is, a digit, a letter, an underscore (`_`) or a dollar sign (`$`). If so, the method returns `true`, and otherwise, it returns `false`.

---

[Page 1374]

Line 21 uses `Character` method `isLetter` to determine whether character `c` is a letter. If so, the method returns `true`, and otherwise, it returns `false`. Line 23 uses `Character` method `isLetterOrDigit` to determine whether character `c` is a letter or a digit. If so, the method returns `true`, and otherwise, it returns `false`.

Line 25 uses `Character` method `isLowerCase` to determine whether character `c` is a lowercase letter. If so, the method returns `true`, and otherwise, it returns `false`. Line 27 uses `Character` method `isUpperCase` to determine whether character `c` is an uppercase letter. If so, the method returns `true`, and otherwise, it returns `false`.

---

[Page 1375]

Line 29 uses `Character` method `toUpperCase` to convert the character `c` to its uppercase equivalent. The method returns the converted character if the character has an uppercase equivalent, and otherwise, the method returns its original argument. Line 31 uses `Character` method `toLowerCase` to convert the character `c` to its lowercase equivalent. The method returns the converted character if the character has a lowercase equivalent, and otherwise, the method returns its original argument.

[Figure 29.16](#) demonstrates static `Character` methods `digit` and `forDigit`, which convert characters to digits and digits to characters, respectively, in different number systems. Common number systems include decimal (base 10), octal (base 8), hexadecimal (base 16) and binary (base 2). The base of a number is also known as its `radix`. For more information on conversions between number systems, see [Appendix E](#).

Figure 29.16. `Character` class `static` conversion methods.

```

1 // Fig. 29.16: StaticCharMethods2.java
2 // Static Character conversion methods.
3 import java.util.Scanner;
4
5 public class StaticCharMethods2
6 {
7 // create StaticCharMethods2 object execute application
8 public static void main(String args[])
9 {
10 Scanner scanner = new Scanner(System.in);
11
12 // get radix
13 System.out.println("Please enter a radix:");
14 int radix = scanner.nextInt();
15
16 // get user choice
17 System.out.printf("Please choose one:\n1 -- %s\n2 -- %s\n",
18 "Convert digit to character", "Convert character to digit");
19 int choice = scanner.nextInt();
20
21 // process request
22 switch (choice)
23 {
24 case 1 : // convert digit to character
25 System.out.println("Enter a digit:");
26 int digit = scanner.nextInt();
27 System.out.printf("Convert digit to character: %s\n",
28 Character.forDigit(digit, radix));
29 break;
30
31 case 2 : // convert character to digit
32 System.out.println("Enter a character:");
33 char character = scanner.next().charAt(0);
34 System.out.printf("Convert character to digit: %s\n",
35 Character.digit(character, radix));
36 break;
37 } // end switch
38 } // end main
39 } // end class StaticCharMethods2

```

```

Please enter a radix:
16
Please choose one:
1 -- Convert digit to character
2 -- Convert character to digit
2
Enter a character:
A
Convert character to digit: 10

```

```
Please enter a radix:
16
Please choose one:
1 -- Convert digit to character
2 -- Convert character to digit
1
Enter a digit:
13
Convert digit to character: d
```

Line 28 uses method `forDigit` to convert the integer `digit` into a character in the number system specified by the integer `radix` (the base of the number). For example, the decimal integer `13` in base `16` (the `radix`) has the character value `'d'`. Note that lowercase letters represent the same value as uppercase letters in number systems. Line 35 uses method `digit` to convert the character `c` into an integer in the number system specified by the integer `radix` (the base of the number). For example, the character `'A'` is the base `16` (the `radix`) representation of the base `10` value `10`. The radix must be between `2` and `36`, inclusive.

---

[Page 1376]

The application in [Fig. 29.17](#) demonstrates the constructor and several non-static methods of class `Character` `charValue`, `toString` and `equals`. Lines 89 instantiate two `Character` objects and pass character literals to the constructor to initialize those objects. Line 12 uses `Character` method `charValue` to return the `char` value stored in `Character` object `c1`. Line 12 returns a string representation of `Character` object `c2` using method `toString`. The condition in the `if... else` statement at lines 14-17 uses method `equals` to determine whether the object `c1` has the same contents as the object `c2` (i.e., the characters inside each object are equal).

Figure 29.17. `Character` class non-`static` methods.

(This item is displayed on page 1377 in the print version)

```
1 // Fig. 29.17: OtherCharMethods.java
2 // Non-static Character methods.
3
4 public class OtherCharMethods
5 {
6 public static void main(String args[])
7 {
8 Character c1 = 'A';
9 Character c2 = 'a';
10
11 System.out.printf(
12 "c1 = %s\nc2 = %s\n\n", c1.charValue(), c2.toString());
13
14 if (c1.equals(c2))
15 System.out.println("c1 and c2 are equal\n");
16 else
17 System.out.println("c1 and c2 are not equal\n");
18 } // end main
19 } // end class OtherCharMethods
```

```
c1 = A
c2 = a

c1 and c2 are not equal
```

[< PREV](#)[NEXT >](#)

## 29.6. Class `StringTokenizer`

When you read a sentence, your mind breaks the sentence into **tokens** individual words and punctuation marks, each of which conveys meaning to you. Compilers also perform tokenization. They break up statements into individual pieces like keywords, identifiers, operators and other elements of a programming language. In this section, we study Java's `StringTokenizer` class (from package `java.util`), which breaks a string into its component tokens. Tokens are separated from one another by **delimiters**, typically whitespace characters such as space, tab, newline and carriage return. Other characters can also be used as delimiters to separate tokens. The application in [Fig. 29.18](#) demonstrates class `StringTokenizer`.

---

[Page 1377]

Figure 29.18. `StringTokenizer` object used to tokenize strings.

(This item is displayed on page 1378 in the print version)

```
1 // Fig. 29.18: TokenTest.java
2 // StringTokenizer class.
3 import java.util.Scanner;
4 import java.util.StringTokenizer;
5
6 public class TokenTest
7 {
8 // execute application
9 public static void main(String args[])
10 {
11 // get sentence
12 Scanner scanner = new Scanner(System.in);
13 System.out.println("Enter a sentence and press Enter");
14 String sentence = scanner.nextLine();
15
16 // process user sentence
17 StringTokenizer tokens = new StringTokenizer(sentence);
18 System.out.printf("Number of elements: %d\nThe tokens are:\n",
19 tokens.countTokens());
20
21 while (tokens.hasMoreTokens())
22 System.out.println(tokens.nextToken());
23 } // end main
24 } // end class TokenTest
```

```
Enter a sentence and press Enter
This is a sentence with seven tokens
Number of elements: 7
The tokens are:
This
is
a
sentence
with
seven
tokens
```

When the user presses the *Enter* key, the input sentence is stored in `String` variable `sentence`. Line 17 creates an instance of class `StringTokenizer` using `String` `sentence`. This `StringTokenizer` constructor takes a string argument and creates a `StringTokenizer` for it, and will use the default delimiter string `"\t\n\r\f"` consisting of a space, a tab, a carriage return and a newline for tokenization. There are two other constructors for class `StringTokenizer`. In the version that takes two `String` arguments, the second `String` is the delimiter string. In the version that takes three arguments, the second `String` is the delimiter string and the third argument (a `boolean`) determines whether the delimiters are also returned as tokens (only if the argument is `TRUE`). This is useful if you need to know what the delimiters are.

Line 19 uses `StringTokenizer` method `countTokens` to determine the number of tokens in the string to be tokenized. The condition in the `while` statement at lines 21-22 uses `StringTokenizer` method `hasMoreTokens` to determine whether there are more tokens in the string being tokenized. If so, line 22 prints the next token in the `String`. The next token is obtained with a call to `StringTokenizer` method `nextToken`, which returns a `String`. The token is output using `println`, so subsequent tokens appear on separate lines.

---

[Page 1378]

If you would like to change the delimiter string while tokenizing a string, you may do so by specifying a new delimiter string in a `nextToken` call as follows:

```
tokens.nextTokn(newDelimiterString);
```

This feature is not demonstrated in [Fig. 29.18](#).

## 29.7. Regular Expressions, Class Pattern and Class Matcher

**Regular expressions** are sequences of characters and symbols that define a set of strings. They are useful for validating input and ensuring that data is in a particular format. For example, a ZIP code must consist of five digits, and a last name must contain only letters, spaces, apostrophes and hyphens. One application of regular expressions is to facilitate the construction of a compiler. Often, a large and complex regular expression is used to validate the syntax of a program. If the program code does not match the regular expression, the compiler knows that there is a syntax error within the code.

Class `String` provides several methods for performing regular-expression operations, the simplest of which is the matching operation. `String` method `matches` receives a string that specifies the regular expression and matches the contents of the `String` object on which it is called to the regular expression. The method returns a `boolean` indicating whether the match succeeded.

A regular expression consists of literal characters and special symbols. [Figure 29.19](#) specifies some **predefined character classes** that can be used with regular expressions. A character class is an escape sequence that represents a group of characters. A digit is any numeric character. A **word character** is any letter (uppercase or lowercase), any digit or the underscore character. A whitespace character is a space, a tab, a carriage return, a newline or a form feed. Each character class matches a single character in the string we are attempting to match with the regular expression.

Figure 29.19. Predefined character classes.

Character	Matches	Character	Matches
<code>\d</code>	any digit	<code>\D</code>	any non-digit
<code>\w</code>	any word character	<code>\W</code>	any non-word character
<code>\s</code>	any whitespace	<code>\S</code>	any non-whitespace

Regular expressions are not limited to these predefined character classes. The expressions employ various operators and other forms of notation to match complex patterns. We examine several of these techniques in the application in [Fig. 29.20](#) and [Fig. 29.21](#) which validates user input via regular expressions. [*Note:* This application is not designed to match all possible valid user input.]

Figure 29.20. Validating user information using regular expressions.

(This item is displayed on page 1380 in the print version)

```

Validate Result:
Valid input. Thank you.
```

[Figure 29.20](#) validates user input. Line 9 validates the first name. To match a set of characters that does not have a predefined character class, use square brackets, `[]`. For example, the pattern `"[aeiou]"` matches a single character that is a vowel. Ranges of characters can be represented by placing a dash (`-`) between two characters. In the example, `"[A-Z]"` matches a single uppercase letter. If the first character in the brackets is `"^"`, the expression accepts any character other than those indicated. However, it is important to note that `"[^Z]"` is not the same as `"[A-Y]"`, which matches uppercase letters AY. `"[^Z]"` matches any character other than capital Z, including lowercase letters and non-letters such as the newline character. Ranges in character classes are determined by the letters' integer values. In this example, `"[A-Za-z]"` matches all uppercase and lowercase letters. The range `"[A-z]"` matches all letters and also matches those characters (such as `%` and `6`) with an integer value between uppercase Z and lowercase a (for more information on integer values of characters see [Appendix B](#), ASCII Character Set). Like predefined character classes, character classes delimited by square brackets match a single character in the search object.

In line 9, the asterisk after the second character class indicates that any number of letters can be matched. In general, when the regular-expression operator `"*"` appears in a regular expression, the application attempts to match zero or more occurrences of the subexpression immediately preceding the `"*"`. Operator `"+"` attempts to match one or more occurrences of the subexpression immediately preceding `"+"`. So both `"A*"` and `"A+"` will match `"AAA"`, but only `"A*"` will match an empty string.

If method `validateFirstName` returns `True` (line 29), the application attempts to validate the last name (line 31) by calling `validateLastName` (lines 1316 of [Fig. 29.20](#)). The regular expression to validate the last name matches any number of letters split by spaces, apostrophes or hyphens.

Line 33 validates the address by calling method `validateAddress` (lines 1923 of [Fig. 29.20](#)). The first character class matches any digit one or more times (`\\d+`). Note that two `\` characters are used because `\` normally starts an escape sequences in a string. So `\\d` in a Java string represents the regular expression pattern `\d`. Then we match one or more whitespace characters (`\\s+`). The character `"|"` allows a match of the expression to its left or to its right. For example, `"Hi (John|Jane)"` matches both `"Hi John"` and `"Hi Jane"`. The parentheses are used to group parts of the regular expression. In this example, the left side of `|` matches a single word, and the right side matches two words separated by any amount of white space. So the address must contain a number followed by one or two words. Therefore, `"10 Broadway"` and `"10 Main Street"` are both valid addresses in this example. The city (line 2629 of [Fig. 29.20](#)) and state (line 3235 of [Fig. 29.20](#)) methods also match any word of at least one character or, alternatively, any two words of at least one character if the words are separated by a single space. This means both `Waltham` and `West Newton` would match.

The asterisk (`*`) and plus (`+`) are formally called **quantifiers**. [Figure 29.22](#) lists all the quantifiers. We have already discussed how the asterisk (`*`) and plus (`+`) quantifiers work. All quantifiers affect only the subexpression immediately preceding the quantifier. Quantifier question mark (`?`) matches zero or one occurrences of the expression that it quantifies. A set of braces containing one number (`{n}`) matches exactly `n` occurrences of the expression it quantifies. We demonstrate this quantifier to validate the zip code in [Fig. 29.20](#) at line 40. Including a comma after the number enclosed in braces matches at least `n` occurrences of the quantified expression. The set of braces containing two numbers (`{n, m}`), matches between `n` and `m` occurrences of the expression that it qualifies. Quantifiers may be applied to patterns enclosed in parentheses to create more complex regular expressions.

Figure 29.22. Quantifiers used in regular expressions.

Quantifier	Matches
<code>*</code>	Matches zero or more occurrences of the pattern.
<code>+</code>	Matches one or more occurrences of the pattern.
<code>?</code>	Matches zero or one occurrences of the pattern.

Quantifier	Matches
{ <i>n</i> }	Matches exactly <i>n</i> occurrences.
{ <i>n</i> , }	Matches at least <i>n</i> occurrences.
{ <i>n</i> , <i>m</i> }	Matches between <i>n</i> and <i>m</i> (inclusive) occurrences.

All of the quantifiers are **greedy**. This means that they will match as many occurrences as they can as long as the match is still successful. However, if any of these quantifiers is followed by a question mark (?), the quantifier becomes **reluctant** (sometimes called **lazy**). It then will match as few occurrences as possible as long as the match is still successful.

The zip code (line 40 in [Fig. 29.20](#)) matches a digit five times. This regular expression uses the digit character class and a quantifier with the digit 5 between braces. The phone number (line 46 in [Fig. 29.20](#)) matches three digits (the first one cannot be zero) followed by a dash followed by three more digits (again the first one cannot be zero) followed by four more digits.

`String` Method `matches` checks whether an entire string conforms to a regular expression. For example, we want to accept "Smith" as a last name, but not "9@Smith#". If only a substring matches the regular expression, method `matches` returns `false`.

## Replacing Substrings and Splitting Strings

Sometimes it is useful to replace parts of a string or to split a string into pieces. For this purpose, class `String` provides methods `replaceAll`, `replaceFirst` and `split`. These methods are demonstrated in [Fig. 29.23](#).

Figure 29.23. Methods `replaceFirst`, `replaceAll` and `split`.

(This item is displayed on pages 1384 - 1385 in the print version)

```
1 // Fig. 29.23: RegexSubstitution.java
2 // Using methods replaceFirst, replaceAll and split.
3
4 public class RegexSubstitution
5 {
6 public static void main(String args[])
7 {
8 String firstString = "This sentence ends in 5 stars *****";
9 String secondString = "1, 2, 3, 4, 5, 6, 7, 8";
10
11 System.out.printf("Original String 1: %s\n", firstString);
12
13 // replace '*' with '^'
14 firstString = firstString.replaceAll("*" , "^");
15
16 System.out.printf("^ substituted for *: %s\n", firstString);
17
18 // replace 'stars' with 'carets'
19 firstString = firstString.replaceAll("stars", "carets");
20
21 System.out.printf(
22 "\"carets\" substituted for \"stars\": %s\n", firstString);
23 }
```

```

24 // replace words with 'word'
25 System.out.printf("Every word replaced by \"%word\": %s\n\n",
26 firstString.replaceAll("\\w+", "word"));
27
28 System.out.printf("Original String 2: %s\n", secondString);
29
30 // replace first three digits with 'digit'
31 for (int i = 0; i < 3; i++)
32 secondString = secondString.replaceFirst("\\d", "digit");
33
34 System.out.printf(
35 "First 3 digits replaced by \"%digit\" : %s\n", secondString);
36 String output = "String split at commas: [" ;
37
38 String[] results = secondString.split(",\\s*"); // split on commas
39
40 for (String string : results)
41 output += "\"" + string + "\", "; // output results
42
43 // remove the extra comma and add a bracket
44 output = output.substring(0, output.length() - 2) + "];";
45 System.out.println(output);
46 } // end main
47 } // end class RegexSubstitution

```

```

Original String 1: This sentence ends in 5 stars *****
^ substituted for *: This sentence ends in 5 stars ^^^^^
"carets" substituted for "stars": This sentence ends in 5 carets ^^^^^
Every word replaced by "word": word word word word word word ^^^^^

Original String 2: 1, 2, 3, 4, 5, 6, 7, 8
First 3 digits replaced by "digit" : digit, digit, digit, 4, 5, 6, 7, 8
String split at commas: ["digit", "digit", "digit", "4", "5", "6", "7", "8"]

```

Method `replaceAll` replaces text in a string with new text (the second argument) wherever the original string matches a regular expression (the first argument). Line 14 replaces every instance of `"**"` in `firstString` with `"^"`. Note that the regular expression (`"\\**"`) precedes character `*` with two backslashes, `\\`. Normally, `*` is a quantifier indicating that a regular expression should match any number of occurrences of a preceding pattern. However, in line 14, we want to find all occurrences of the literal character `*` to do this, we must escape character `*` with character `\\`. By escaping a special regular-expression character with a `\\`, we instruct the regular-expression matching engine to find the actual character, as opposed to what it represents in a regular expression. Since the expression is stored in a Java string and `\\` is a special character in Java strings, we must include an additional `\\`. So the Java string `"\\**"` represents the regular-expression pattern `\\*` which matches a single `*` character in the search string. In line 19, every match for the regular expression `"stars"` in `firstString` is replaced with `"carets"`.

Method `replaceFirst` (line 32) replaces the first occurrence of a pattern match. Java `Strings` are immutable,

therefore method `replaceFirst` returns a new string in which the appropriate characters have been replaced. This line takes the original string and replaces it with the string returned by `replaceFirst`. By iterating three times we replace the first three instances of a digit (`\d`) in `secondString` with the text `"digit"`.

Method `split` divides a string into several substrings. The original string is broken in any location that matches a specified regular expression. Method `split` returns an array of strings containing the substrings between matches for the regular expression. In line 38, we use method `split` to tokenize a string of comma-separated integers. The argument is the regular expression that locates the delimiter. In this case, we use the regular expression `",\\s+"` to separate the substrings wherever a comma occurs. By matching any whitespace characters, we eliminate extra spaces from the resulting substrings. Note that the commas and whitespace are not returned as part of the substrings. Again, note that the Java string `",\\s+"` represents the regular expression `,\\s*`.

## Classes `Pattern` and `Matcher`

In addition to the regular-expression capabilities of class `String`, Java provides other classes in package `java.util.regex` that help developers manipulate regular expressions. Class `Pattern` represents a regular expression. Class `Matcher` contains both a regular-expression pattern and a `CharSequence` in which to search for the pattern.

`CharSequence` is an interface that allows read access to a sequence of characters. The interface requires that the methods `charAt`, `length`, `subSequence` and `toString` be declared. Both `String` and `StringBuffer` implement interface `CharSequence`, so an instance of either of these classes can be used with class `Matcher`.

### Common Programming Error 29.4

*A regular expression can be tested against an object of any class that implements interface `CharSequence`, but the regular expression must be a `String`. Attempting to create a regular expression as a `StringBuffer` is an error.*

---

[Page 1386]

If a regular expression will be used only once, static `Pattern` method `matches` can be used. This method takes a string that specifies the regular expression and a `CharSequence` on which to perform the match. This method returns a `boolean` indicating whether the search object (the second argument) matches the regular expression.

If a regular expression will be used more than once, it is more efficient to use static `Pattern` method `compile` to create a specific `Pattern` object for that regular expression. This method receives a string representing the pattern and returns a new `Pattern` object, which can then be used to call method `matcher`. This method receives a `CharSequence` to search and returns a `Matcher` object.

`Matcher` provides method `matches`, which performs the same task as `Pattern` method `matches`, but receives no arguments; the search pattern and search object are encapsulated in the `Matcher` object. Class `Matcher` provides other methods, including `find`, `lookingAt`, `replaceFirst` and `replaceAll`.

[Figure 29.24](#) presents a simple example that employs regular expressions. This program matches birthdays against a regular expression. The expression only matches birthdays that do not occur in April and that belong to people whose names begin with `"J"`.

Lines 11-12 create a `Pattern` by invoking static `Pattern` method `compile`. The dot character `"."` in the regular expression (line 12) matches any single character except a new-line character.

Figure 29.24. Regular expressions checking birthdays.

```
1 // Fig. 29.24: RegexMatches.java
2 / Demonstrating Classes Pattern and Matcher.
3 import java.util.regex.Matcher;
4 import java.util.regex.Pattern;
5
6 public class RegexMatches
7 {
8 public static void main(String args[])
9 {
10 // create regular expression
11 Pattern expression =
12 Pattern.compile("J.*\\d[0-35-9]-\\d\\d-\\d\\d\\d");
13
14 String string1 = "Jane's Birthday is 05-12-75\n" +
15 "Dave's Birthday is 11-04-68\n" +
16 "John's Birthday is 04-28-73\n" +
17 "Joe's Birthday is 12-17-77";
18
19 // match regular expression to string and print matches
20 Matcher matcher = expression.matcher(string1);
21
22 while (matcher.find())
23 System.out.println(matcher.group());
24 } // end main
25 } // end class RegexMatches
```

```
Jane's Birthday is 05-12-75
Joe's Birthday is 12-17-77
```

Line 20 creates the `Matcher` object for the compiled regular expression and the matching sequence (`string1`). Lines 22-23 use a `while` loop to iterate through the string. Line 22 uses `Matcher` method `find` to attempt to match a piece of the search object to the search pattern. Each call to this method starts at the point where the last call ended, so multiple matches can be found. `Matcher` method `lookingAt` performs the same way, except that it always starts from the beginning of the search object and will always find the first match if there is one.

## Common Programming Error 29.5

*Method `matches` (from class `String`, `Pattern` or `Matcher`) will return `true` only if the entire search object matches the regular expression. Methods `find` and `lookingAt` (from class `Matcher`) will return `TRUE` if a portion of the search object matches the regular expression.*

Line 23 uses `Matcher` method `group`, which returns the string from the search object that matches the search pattern. The string that is returned is the one that was last matched by a call to `find` or `lookingAt`. The output in [Fig. 29.24](#) shows the two matches that were found in `string1`.

## Regular Expression Web Resources

This section presents several of Java's regular-expression capabilities. The following Web sites provide more information on regular expressions.

[developer.java.sun.com/developer/technicalArticles/releases/1.4regex](http://developer.java.sun.com/developer/technicalArticles/releases/1.4regex)

Thoroughly describes Java's regular-expression capabilities.

## 29.8. Wrap-Up

In this chapter, you learned about more `String` methods for selecting portions of `Strings` and manipulating `Strings`. You also learned about the `Character` class and some of the methods it declares to handle `chars`. The chapter also discussed the capabilities of the `StringBuffer` class for creating `Strings`. The end of the chapter discussed regular expressions which provide a powerful capability to search and match portions of `Strings` that fit a particular pattern.

## Summary

- A character literal's value is its integer value in the Unicode character set. Strings can include letters, digits and special characters such as `+`, `-`, `*`, `/` and `$`. A string in Java is an object of class `String`. `String` literals are often referred to as `String` objects and are written in double quotes in a program.
  - `string` objects are immutabletheir character contents cannot be changed after they are created.
  - `string` method `length` returns the number of characters in a `String`.
  - `string` method `charAt` returns the character at a specific position.
  - `string` method `equals` tests any two objects for equality. The method returns `true` if the contents of the `Strings` are equal, `false` otherwise. Method `equals` uses a lexicographical comparison for `StringS`.
- 

- When primitive-type values are compared with `==`, the result is `true` if both values are identical. When references are compared with `==`, the result is true if both references refer to the same object in memory.
- Java treats all string literals with the same contents as a single `String` object.
- `string` method `equalsIgnoreCase` performs a case-insensitive string comparison.
- `string` method `compareTo` uses a lexicographical comparison and returns 0 if the strings it is comparing are equal, a negative number if the string `compareTo` is invoked on is less than the `String` that is passed as an argument and a positive number if the string that `compareTo` is invoked on is greater than the string that is passed as an argument.
- `string` method `regionMatches` compares portions of two strings for equality.
- `string` method `startsWith` determines whether a string starts with the characters specified as an argument. `String` method `endsWith` determines whether a string ends with the characters specified as an argument.
- `string` method `indexOf` locates the first occurrence of a character or a substring in a string. `String` method `lastIndexOf` locates the last occurrence of a character or a substring in a string.
- `string` method `substring` copies and returns part of an existing string object.
- `string` method `concat` concatenates two string objects and returns a new string object containing the characters from both original strings.
- `string` method `replace` returns a new string object that replaces every occurrence in a `String` of its first character argument with its second character argument.
- `string` method `toUpperCase` returns a new string with uppercase letters in the positions where the original string had lowercase letters. `String` method `toLowerCase` returns a new string with lowercase letters in the positions where the original `string` had uppercase letters.
- `string` method `Trim` returns a new string object in which all whitespace characters (e.g., spaces, newlines and tabs) have been removed from the beginning and end of a string.
- `string` method `toCharArray` returns a char array containing a copy of the string's characters.

- `String` class static method `valueOf` returns its argument converted to a `String`.
- Class `StringBuffer` provides constructors that enable `StringBuffers` to be initialized with no characters and an initial capacity of 16 characters, with no characters and an initial capacity specified in the integer argument, or with a copy of the characters of the `String` argument and an initial capacity that is the number of characters in the `String` argument plus 16.
- `StringBuffer` method `length` returns the number of characters currently stored in a `StringBuffer`. `StringBuffer` method `capacity` returns the number of characters that can be stored in a `StringBuffer` without allocating more memory.
- `StringBuffer` method `ensureCapacity` ensures that a `StringBuffer` has at least the specified capacity. `StringBuffer` method `setLength` increases or decreases the length of a `StringBuffer`.
- `StringBuffer` method `charAt` returns the character at the specified index. `StringBuffer` method `setCharAt` sets the character at the specified position. `StringBuffer` method `getChars` copies characters in the `StringBuffer` into the character array passed as an argument.
- Class `StringBuffer` provides overloaded append methods to add primitive-type, character array, `String`, `Object` and `CharSequence` values to the end of a `StringBuffer`. `StringBuffers` and the append methods are used by the Java compiler to implement the `+` and `+=` concatenation operators.
- Class `StringBuffer` provides overloaded `insert` methods to insert primitive-type, character array, `String`, `Object` and `CharSequence` values at any position in a `StringBuffer`.
- Class `Character` provides a constructor that takes a `char` argument.

---

[Page 1389]

- `Character` method `isDefined` determines whether a character is defined in the Unicode character set. If so, the method returns `true` otherwise, it returns `false`.
- `Character` method `isDigit` determines whether a character is a defined Unicode digit. If so, the method returns `true` otherwise, it returns `false`.
- `Character` method `isJavaIdentifierStart` determines whether a character can be used as the first character of an identifier in Java [i.e., a letter, an underscore (`_`) or a dollar sign (`$`)]. If so, the method returns `TRUE` otherwise, it returns `false`.
- `Character` method `isJavaIdentifierPart` determines whether a character can be used in an identifier in Java [i.e., a digit, a letter, an underscore (`_`) or a dollar sign (`$`)]. `Character` method `isLetter` determines whether a `character` is a letter. `Character` method `isLetterOrDigit` determines whether a character is a letter or a digit. In each case, if so, the method returns `TRUE` otherwise, it returns `false`.
- `Character` method `isLowerCase` determines whether a character is a lowercase letter. `Character` method `isUpperCase` determines whether a character is an uppercase letter. In both cases, if so, the method returns `true` otherwise, `false`.
- `Character` method `toUpperCase` converts a character to its uppercase equivalent. `Character` method `toLowerCase` converts a character to its lowercase equivalent.
- `Character` method `digit` converts its character argument into an integer in the number system specified by its integer argument `radix`. `Character` method `forDigit` converts its integer argument `digit` into a character in the number system specified by its integer argument `radix`.
- `Character` method `charValue` returns the `char` stored in a `Character` object. `Character` method `toString` returns a `String` representation of a `Character`.
- `StringTokenizer`'s default constructor creates a `StringTokenizer` for its string argument that will use the default delimiter string `"\t\n\r\f"`, consisting of a space, a tab, a newline and a carriage return for tokenization.
- `StringTokenizer` method `countTokens` returns the number of tokens in a string to be tokenized.

- `stringTokenizer` method `hasMoreTokens` determines whether there are more tokens in the string being tokenized.
- `stringTokenizer` method `nextToken` returns a `String` with the next token.
- Regular expressions are sequences of characters and symbols that define a set of strings. They are useful for validating input and ensuring that data is in a particular format.
- `string` method `matches` receives a string that specifies the regular expression and matches the contents of the `String` object on which it is called to the regular expression. The method returns a boolean indicating whether the match succeeded.
- A character class is an escape sequence that represents a group of characters. Each character class matches a single character in the string we are attempting to match with the regular expression.
- A word character (`\w`) is any letter (uppercase or lowercase), any digit or the underscore character.
- A whitespace character (`\s`) is a space, a tab, a carriage return, a newline or a form feed.
- A digit (`\d`) is any numeric character.
- To match a set of characters that does not have a predefined character class, use square brackets, `[]`. Ranges of characters can be represented by placing a dash (`-`) between two characters. If the first character in the brackets is `^`, the expression accepts any character other than those indicated.
- When the regular expression operator `*` appears in a regular expression, the program attempts to match zero or more occurrences of the subexpression immediately preceding the `*`.

---

[Page 1390]

- Operator `+` attempts to match one or more occurrences of the subexpression preceding it.
- The character `|` allows a match of the expression to its left or to its right.
- The parentheses `()` are used to group parts of the regular expression.
- The asterisk `*` and plus `+` are formally called quantifiers.
- All quantifiers affect only the subexpression immediately preceding the quantifier.
- Quantifier question mark `?` matches zero or one occurrences of the expression that it quantifies.
- A set of braces containing one number `{n}` matches exactly `n` occurrences of the expression it quantifies.
- Including a comma after the number enclosed in braces matches at least `n` occurrences of the quantified expression.
- A set of braces containing two numbers `{n, m}` matches between `n` and `m` occurrences of the expression that it quantifies.
- All of the quantifiers are greedy, which means that they will match as many occurrences as they can as long as the match is successful.
- If any of these quantifiers is followed by a question mark `?`, the quantifier becomes reluctant, matching as few occurrences as possible as long as the match is successful.
- `string` method `replaceAll` replaces text in a string with new text (the second argument) wherever the original string matches a regular expression (the first argument).
- Escaping a special regular-expression character with a `\` instructs the regular-expression matching engine to find the actual character, as opposed to what it represents in a regular expression.

- `String` method `replaceFirst` replaces the first occurrence of a pattern match. Java `Strings` are immutable, therefore method `replaceFirst` returns a new string in which the appropriate characters have been replaced.
- `String` method `split` divides a string into several substrings. The original string is broken in any location that matches a specified regular expression. Method `split` returns an array of strings containing the substrings between matches for the regular expression.
- Class `Pattern` represents a regular expression.
- Class `Matcher` contains both a regular-expression pattern and a `CharSequence` in which to search for the pattern.
- `CharSequence` is an interface that allows read access to a sequence of characters. Both `String` and `StringBuffer` implement interface `CharSequence`, so an instance of either of these classes can be used with class `Matcher`.
- If a regular expression will be used only once, static `Pattern` method `matches` takes a string that specifies the regular expression and a `CharSequence` on which to perform the match. This method returns a boolean indicating whether the search object matches the regular expression.
- If a regular expression will be used more than once, it is more efficient to use static `Pattern` method `compile` to create a specific `Pattern` object for that regular expression. This method receives a string representing the pattern and returns a new `Pattern` object.
- `Pattern` method `matcher` receives a `CharSequence` to `search` and returns a `Matcher` object.
- `Matcher` method `matches` performs the same task as `Pattern` method `matches`, but receives no arguments.
- `Matcher` method `find` attempts to match a piece of the search object to the search pattern. Each call to this method starts at the point where the last call ended, so multiple matches can be found.
- `Matcher` method `lookingAt` performs the same as `find`, except that it always starts from the beginning of the search object and will always find the first match if there is one.

---

[Page 1391]

- `Matcher` method `group` returns the string from the search object that matches the search pattern. The string that is returned is the one that was last matched by a call to `find` or `lookingAt`.

## Self-Review Exercises

29.1 State whether each of the following is *true* or *false*. If *false*, explain why.

- a. When `String` objects are compared using `==`, the result is `true` if the `Strings` contain the same values.
- b. A `String` can be modified after it is created.

29.2 For each of the following, write a single statement that performs the indicated task:

- a. Compare the string in `s1` to the string in `s2` for equality of contents.
- b. Append the string `s2` to the string `s1`, using `+=`.
- c. Determine the length of the string in `s1`.

## Answers to Self-Review Exercises

### 29.1

- a. False. `String` objects that are compared using operator `==` are compared to determine whether they are the same object in memory.
- b. False. `String` objects are immutable and cannot be modified after they are created. `StringBuffer` objects can be modified after they are created.

### 29.2

- a. `s1.equals( s2 )`
- b. `s1 += s2;`
- c. `s1.length()`

## Exercises

- 29.3 Write an application that uses `String` method `compareTo` to compare two strings input by the user. Output whether the first string is less than, equal to or greater than the second.
- 29.4 Write an application that uses `String` method `regionMatches` to compare two strings input by the user. The application should input the number of characters to be compared and the starting index of the comparison. The application should state whether the strings are equal. Ignore the case of the characters when performing the comparison.
- 29.5 Write an application that uses random-number generation to create sentences. Use four arrays of strings called `article`, `noun`, `verb` and `preposition`. Create a sentence by selecting a word at random from each array in the following order: `article`, `noun`, `verb`, `preposition`, `article` and `noun`. As each word is picked, concatenate it to the previous words in the sentence. The words should be separated by spaces. When the final sentence is output, it should start with a capital letter and end with a period. The application should generate 20 sentences and output them to a text area.

The article array should contain the articles "the", "a", "one", "some" and "any"; the noun array should contain the nouns "boy", "girl", "dog", "town" and "car"; the verb array should contain the verbs "drove", "jumped", "ran", "walked" and "skipped"; the preposition array should contain the prepositions "to", "from", "over", "under" and "on".

After the preceding application is written, modify it to produce a short story consisting of several of these sentences. (How about the possibility of a random term-paper writer?)

- 29.6 (*Limericks*) A limerick is a humorous five-line verse in which the first and second lines rhyme with the fifth, and the third line rhymes with the fourth. Using techniques similar to those developed in [Exercise 29.5](#), write a Java application that produces random limericks. Polishing this application to produce good limericks is a challenging problem, but the result will be worth the effort!
- 29.7 (*Pig Latin*) Write an application that encodes English-language phrases into pig Latin. Pig Latin is a form of coded language. There are many different ways to form pig Latin phrases. For simplicity, use the following algorithm:

To form a pig Latin phrase from an English-language phrase, tokenize the phrase into words with an object of class `StringTokenizer`. To translate each English word into a pig Latin word, place the first letter of the English word at the end of the word and add the letters "ay." Thus, the word "jump" becomes "umpjay," the word "the" becomes "hetay," and the word "computer" becomes "omputercay." Blanks between words remain as blanks. Assume the following: The English phrase consists of words separated by blanks, there are no punctuation marks and all words have two or more letters. Method `printLatinWord` should display each word. Each token returned from `nextToken` is passed to method `printLatinWord` to print the pig Latin word. Enable the user to input the sentence. Keep a running display of all the converted sentences in a text area.

- 29.8 Write an application that inputs a telephone number as a string in the form (555) 555-5555. The application should use an object of class `StringTokenizer` to extract the area code as a token, the first three digits of the phone number as a token and the last four digits of the phone number as a token. The seven digits of the phone number should be concatenated into one string. Both the area code and the phone number should be printed. Remember that you will have to change delimiter characters during the tokenization process.

- 29.9 Write an application that inputs a line of text, tokenizes the line with an object of class `StringTokenizer` and outputs the tokens in reverse order. Use space characters as delimiters.
- 29.10 Use the string-comparison methods discussed in this chapter and the techniques for sorting arrays developed in [Chapter 16](#) to write an application that alphabetizes a list of strings. Allow the user to enter the strings in a text field. Display the results in a text area.
- 29.11 Write an application that inputs a line of text and outputs the text twice: once in all uppercase letters and once in all lowercase letters.
- 29.12 Write an application that inputs a line of text and a search character and uses `String` method `indexOf` to determine the number of occurrences of the character in the text.
- 29.13 Write an application based on the application in [Exercise 29.12](#) that inputs a line of text and uses `String` method `indexOf` to determine the total number of occurrences of each letter of the alphabet in the text. Uppercase and lowercase letters should be counted together. Store the totals for each letter in an array, and print the values in tabular format after the totals have been determined.
- 29.14 Write an application that reads a line of text, tokenizes the line using space characters as delimiters and outputs only those words beginning with the letter "b".
- 29.15 Write an application that reads a line of text, tokenizes it using space characters as delimiters and outputs only those words ending with the letters "ED".
- 29.16 Write an application that inputs an integer code for a character and displays the corresponding character. Modify this application so that it generates all possible three-digit codes in the range from 000 to 255 and attempts to print the corresponding characters.
- 29.17 Write your own versions of `String` search methods `indexOf` and `lastIndexOf`.
- 29.18 Write an application that reads a five-letter word from the user and produces every possible three-letter string that can be derived from the letters of the five-letter word. For example, the three-letter words produced from the word "bathe" include "ate," "bat," "bet," "tab," "hat," "the" and "tea."

## Special Section: Advanced String-Manipulation Exercises

The preceding exercises are keyed to the text and designed to test your understanding of fundamental string-manipulation concepts. This section includes a collection of intermediate and advanced string-manipulation exercises. You should find these problems challenging, yet entertaining. The problems vary considerably in difficulty. Some require an hour or two of application writing and implementation. Others are useful for lab assignments that might require two or three weeks of study and implementation. Some are challenging term projects.

29.19 (*Text Analysis*) The availability of computers with string-manipulation capabilities has resulted in some rather interesting approaches to analyzing the writings of great authors. Much attention has been focused on whether William Shakespeare ever lived. Some scholars believe there is substantial evidence indicating that Christopher Marlowe actually penned the masterpieces attributed to Shakespeare. Researchers have used computers to find similarities in the writings of these two authors. This exercise examines three methods for analyzing texts with a computer.

- a. Write an application that reads a line of text from the keyboard and prints a table indicating the number of occurrences of each letter of the alphabet in the text. For example, the phrase

To be, or not to be: that is the question:

contains one "a," two "b's," no "c's," and so on.

---

[Page 1394]

- b. Write an application that reads a line of text and prints a table indicating the number of one-letter words, two-letter words, three-letter words, and so on, appearing in the text. For example, [Fig. 29.25](#) shows the counts for the phrase

Figure 29.25. Word-length counts for the string "Whether 'tis nobler in the mind to suffer".

Word length	Occurrences
1	0
2	2
3	1
4	2 (including 'tis )
5	0

Word length	Occurrences
6	2
7	1

Whether 'tis nobler in the mind to suffer

- c. Write an application that reads a line of text and prints a table indicating the number of occurrences of each different word in the text. The first version of your application should include the words in the table in the same order in which they appear in the text. For example, the lines

To be, or not to be: that is the question:  
Whether 'tis nobler in the mind to suffer

contain the word "to" three times, the word "be" two times, the word "or" once, and so on. A more interesting (and useful) printout should then be attempted in which the words are sorted alphabetically.

- 29.20 (*Printing Dates in Various Formats*) Dates are printed in several common formats. Two of the more common formats are

04/25/1955 and April 25, 1955

Write an application that reads a date in the first format and prints it in the second format.

- 29.21 (*Check Protection*) Computers are frequently employed in check-writing systems, such as payroll and accounts payable applications. There are many strange stories about weekly paychecks being printed (by mistake) for amounts in excess of \$1 million. Incorrect amounts are printed by computerized check-writing systems because of human error or machine failure. Systems designers build controls into their systems to prevent such erroneous checks from being issued.

Another serious problem is the intentional alteration of a check amount by someone who plans to cash a check fraudulently. To prevent a dollar amount from being altered, some computerized check-writing systems employ a technique called check protection. Checks designed for imprinting by computer contain a fixed number of spaces in which the computer may print an amount. Suppose a paycheck contains eight blank spaces in which the computer is supposed to print the amount of a weekly paycheck. If the amount is large, then all eight of the spaces will be filled. For example,

[Page 1395]            1,230.60 (*check amount*)  
                             -----  
                             12345678 (*position numbers*)

On the other hand, if the amount is less than \$1000, then several of the spaces would ordinarily be left blank. For example,

99.87  
-----  
12345678

contains three blank spaces. If a check is printed with blank spaces, it is easier for someone to alter the amount of the check. To prevent a check from being altered, many check-writing systems insert *leading asterisks* to protect the amount as follows:

\*\*\*99.87  
-----  
12345678

Write an application that inputs a dollar amount to be printed on a check, then prints the amount in check-protected format with leading asterisks if necessary. Assume that nine spaces are available for printing the amount.

- 29.22 (*Writing the Word Equivalent of a Check Amount*) Continuing the discussion in [Exercise 29.21](#), we reiterate the importance of designing check-writing systems to prevent alteration of check amounts. One common security method requires that the check amount be written in numbers and spelled out in words as well. Even if someone is able to alter the numerical amount of the check, it is extremely difficult to change the amount in words. Write an application that inputs a numeric check amount and writes the word equivalent of the amount. For example, the amount 112.43 should be written as

ONE hundred TWELVE and 43/100

- 29.23 (*Morse Code*) Perhaps the most famous of all coding schemes is the Morse code, developed by Samuel Morse in 1832 for use with the telegraph system. The Morse code assigns a series of dots and dashes to each letter of the alphabet, each digit, and a few special characters (e.g., period, comma, colon, semicolon). In sound-oriented systems, the dot represents a short sound and the dash represents a long sound. Other representations of dots and dashes are used with light-oriented systems and signal-flag systems. Separation between words is indicated by a space or, simply, the absence of a dot or dash. In a sound-oriented system, a space is indicated by a short time during which no sound is transmitted. The international version of the Morse code appears in [Fig. 29.26](#).

Figure 29.26. The letters of the alphabet as expressed in international Morse code.

(This item is displayed on page 1396 in the print version)

Character	Code	Character	Code
A	.-	T	-
B	-...	U	..-
C	-.-.	V	...-

Character	Code	Character	Code
D	-..	W	.-.
E	.	X	-..-
F	...-	Y	-.--
G	--.	Z	--..
H	....		
I	..	<i>Digits</i>	
J	.---	1	.----
K	-.-	2	..----
L	.-..	3	...--
M	--	4	....-
N	-.	5	.....
O	---	6	-....
P	.--.	7	--...
Q	--.-	8	----.
R	-.	9	-----
S	...	0	-----

Write an application that reads an English-language phrase and encodes it into Morse code. Also write an application that reads a phrase in Morse code and converts it into the English-language equivalent. Use one blank between each Morse-coded letter and three blanks between each Morse-coded word.

- 29.24 (*Metric Conversion Application*) Write an application that will assist the user with metric conversions. Your application should allow the user to specify the names of the units as strings (i.e., centimeters, liters, grams, etc., for the metric system and inches, quarts, pounds, etc., for the English system) and should respond to simple questions, such as

```
"How many inches are in 2 meters?"
"How many liters are in 10 quarts?"
```

Your application should recognize invalid conversions. For example, the question

```
"How many feet are in 5 kilograms?"
```

## Special Section: Challenging String-Manipulation Projects

- 29.25 *(Project: A Spelling Checker)* Many popular word-processing software packages have built-in spell checkers. In this project, you are asked to develop your own spell-checker utility. We make suggestions to help get you started. You should then consider adding more capabilities. Use a computerized dictionary (if you have access to one) as a source of words.

Why do we type so many words with incorrect spellings? In some cases, it is because we simply do not know the correct spelling, so we make a best guess. In some cases, it is because we transpose two letters (e.g., "defualt" instead of "default"). Sometimes we double-type a letter accidentally (e.g., "hanndy" instead of "handy"). Sometimes we type a nearby key instead of the one we intended (e.g., "biryhday" instead of "birthday"), and so on.

Design and implement a spell-checker application in Java. Your application should maintain an array `wordList` of strings. Enable the user to enter these strings. [*Note:* In [Chapter 14](#), we have introduced file processing. With this capability, you can obtain the words for the spell checker from a computerized dictionary stored in a file.]

Your application should ask a user to enter a word. The application should then look up that word in the `wordList` array. If the word is in the array, your application should print "Word is spelled correctly." If the word is not in the array, your application should print "word is not spelled correctly." Then your application should try to locate other words in `wordList` that might be the word the user intended to type. For example, you can try all possible single transpositions of adjacent letters to discover that the word "default" is a direct match to a word in `wordList`. Of course, this implies that your application will check all other single transpositions, such as "edfault," "dfeault," "deafult," "defalut" and "defaultl." When you find a new word that matches one in `wordList`, print it in a message, such as

---

[Page 1397]

Did you mean "default"?

Implement other tests, such as replacing each double letter with a single letter, and any other tests you can develop to improve the value of your spell checker.

- 29.26 *(Project: A Crossword Puzzle Generator)* Most people have worked a crossword puzzle, but few have ever attempted to generate one. Generating a crossword puzzle is suggested here as a string-manipulation project requiring substantial sophistication and effort.

There are many issues the programmer must resolve to get even the simplest crossword-puzzle-generator application working. For example, how do you represent the grid of a crossword puzzle inside the computer? Should you use a series of strings or two-dimensional arrays?

The programmer needs a source of words (i.e., a computerized dictionary) that can be directly referenced by the application. In what form should these words be stored to facilitate the complex manipulations required by the application?

If you are really ambitious, you will want to generate the clues portion of the puzzle, in which the brief hints for each across word and each down word are printed. Merely printing a version of the blank puzzle itself is not a simple problem.

# Appendix A. Operator Precedence Chart

[Section A.1. Operator Precedence](#)

# A.1. Operator Precedence

Operators are shown in decreasing order of precedence from top to bottom ([Fig. A.1](#)).

Figure A.1. Operator precedence chart.

[Page 1399]

Operator	Description	Associativity
++	unary postfix increment	right to left
--	unary postfix decrement	
++	unary prefix increment	right to left
--	unary prefix decrement	
+	unary plus	
-	unary minus	
!	unary logical negation	
~	unary bitwise complement	
( type )	unary cast	
*	multiplication	left to right
/	division	
%	remainder	
+	addition or string concatenation	left to right
-	subtraction	
<<	left shift	left to right
>>	signed right shift	
>>>	unsigned right shift	
<	less than	left to right
<=	less than or equal to	
>	greater than	
>=	greater than or equal to	
instanceof	type comparison	

Operator	Description	Associativity
<code>==</code>	is equal to	left to right
<code>!=</code>	is not equal to	
<code>&amp;</code>	bitwise AND	left to right
	boolean logical AND	
<code>^</code>	bitwise exclusive OR	left to right
	boolean logical exclusive OR	
<code> </code>	bitwise inclusive OR	left to right
	boolean logical inclusive OR	
<code>&amp;&amp;</code>	conditional AND	left to right
<code>  </code>	conditional OR	left to right
<code>?:</code>	conditional	right to left
<code>=</code>	assignment	right to left
<code>+=</code>	addition assignment	
<code>-=</code>	subtraction assignment	
<code>*=</code>	multiplication assignment	
<code>/=</code>	division assignment	
<code>%=</code>	remainder assignment	
<code>&amp;=</code>	bitwise AND assignment	
<code>^=</code>	bitwise exclusive OR assignment	
<code> =</code>	bitwise inclusive OR assignment	
<code>&lt;&lt;=</code>	bitwise left shift assignment	
<code>&gt;&gt;=</code>	bitwise signed-right-shift assignment	
<code>&gt;&gt;&gt;=</code>	bitwise unsigned-right-shift assignment	

# Appendix B. ASCII Character Set

Figure B.1. ASCII Character Set.

	0	1	2	3	4	5	6	7	8	9
0	nul	soh	stx	etx	eot	enq	ack	bel	bs	ht
1	nl	vt	ff	cr	so	si	dle	dc1	dc2	dc3
2	dc4	nak	syn	etb	can	em	sub	esc	fs	gs
3	rs	us	sp	!	"	#	\$	%	&	'
4	(	)	*	+	,	-	.	/	0	1
5	2	3	4	5	6	7	8	9	:	;
6	<	=	>	?	@	A	B	C	D	E
7	F	G	H	I	J	K	L	M	N	O
8	P	Q	R	S	T	U	V	W	X	Y
9	Z	[	\	]	^	_	'	a	b	c
10	d	e	f	g	h	i	j	k	l	m
11	n	o	p	q	r	s	t	u	v	w
12	x	y	z	{		}	~	del		

The digits at the left of the table are the left digits of the decimal equivalent (0127) of the character code, and the digits at the top of the table are the right digits of the character code. For example, the character code for "F" is 70, and the character code for "&" is 38.

Most users of this book are interested in the ASCII character set used to represent English characters on many computers. The ASCII character set is a subset of the Unicode character set used by Java to represent characters from most of the world's languages. For more information on the Unicode character set, see [Appendix F](#).

# Appendix C. Keywords and Reserved Words

Figure C.1. Java keywords.

Java Keywords				
<code>abstract</code>	<code>assert</code>	<code>boolean</code>	<code>break</code>	<code>byte</code>
<code>case</code>	<code>catch</code>	<code>char</code>	<code>class</code>	<code>continue</code>
<code>default</code>	<code>do</code>	<code>double</code>	<code>else</code>	<code>enum</code>
<code>extends</code>	<code>final</code>	<code>finally</code>	<code>float</code>	<code>for</code>
<code>if</code>	<code>implements</code>	<code>import</code>	<code>instanceof</code>	<code>int</code>
<code>interface</code>	<code>long</code>	<code>native</code>	<code>new</code>	<code>package</code>
<code>private</code>	<code>protected</code>	<code>public</code>	<code>return</code>	<code>short</code>
<code>static</code>	<code>strictfp</code>	<code>super</code>	<code>switch</code>	<code>synchronized</code>
<code>this</code>	<code>throw</code>	<code>throws</code>	<code>transient</code>	<code>try</code>
<code>void</code>	<code>volatile</code>	<code>while</code>		
<i>Keywords that are not currently used</i>				
<code>const</code>	<code>goto</code>			

Java also contains the reserved words `true` and `false`, which are `boolean` literals, and `null`, which is the literal that represents a reference to nothing. Like keywords, these reserved words cannot be used as identifiers.

# Appendix D. Primitive Types

Figure D.1. Java primitive types.

Type	Size in bits	Values	Standard
<code>boolean</code>		<code>true</code> or <code>false</code>	
[Note: A <code>boolean</code> 's representation is specific to the Java Virtual Machine on each platform.]			
<code>char</code>	16	'\u0000' to '\uFFFF' (0 to 65535)	(ISO Unicode character set)
<code>byte</code>	8	128 to +127 ( $2^7$ to $2^7 - 1$ )	
<code>short</code>	16	32,768 to +32,767 ( $2^{15}$ to $2^{15} - 1$ )

# Appendix G. Using the Java API Documentation

[Section G.1. Introduction](#)

[Section G.2. Navigating the Java API](#)

## G.1. Introduction

The Java class library contains thousands of predefined classes and interfaces that programmers can use to write their own applications. These classes are grouped into packages based on their functionality. For example, the classes and interfaces used for file processing are grouped into the `java.io` package, and the classes and interfaces for networking applications are grouped into the `java.net` package. The [Java API documentation](#) lists the `public` and `protected` members of each class and the `public` members of each interface in the Java class library. The documentation overviews all the classes and interfaces, summarizes their members (i.e., the fields, constructors and methods of classes, and the fields and methods of interfaces) and provides detailed descriptions of each member. Most Java programmers rely on this documentation when writing programs. Normally, programmers would search the API to find the following:

1. The package that contains a particular class or interface.
2. Relationships between a particular class or interface and other classes and interfaces.
3. Class or interface constants normally declared as `public static final` fields.
4. Constructors to determine how an object of the class can be initialized.
5. The methods of a class to determine whether they are `static` or non-`static`, the number and types of the arguments you need to pass, the return types and any exceptions that might be thrown from the method.

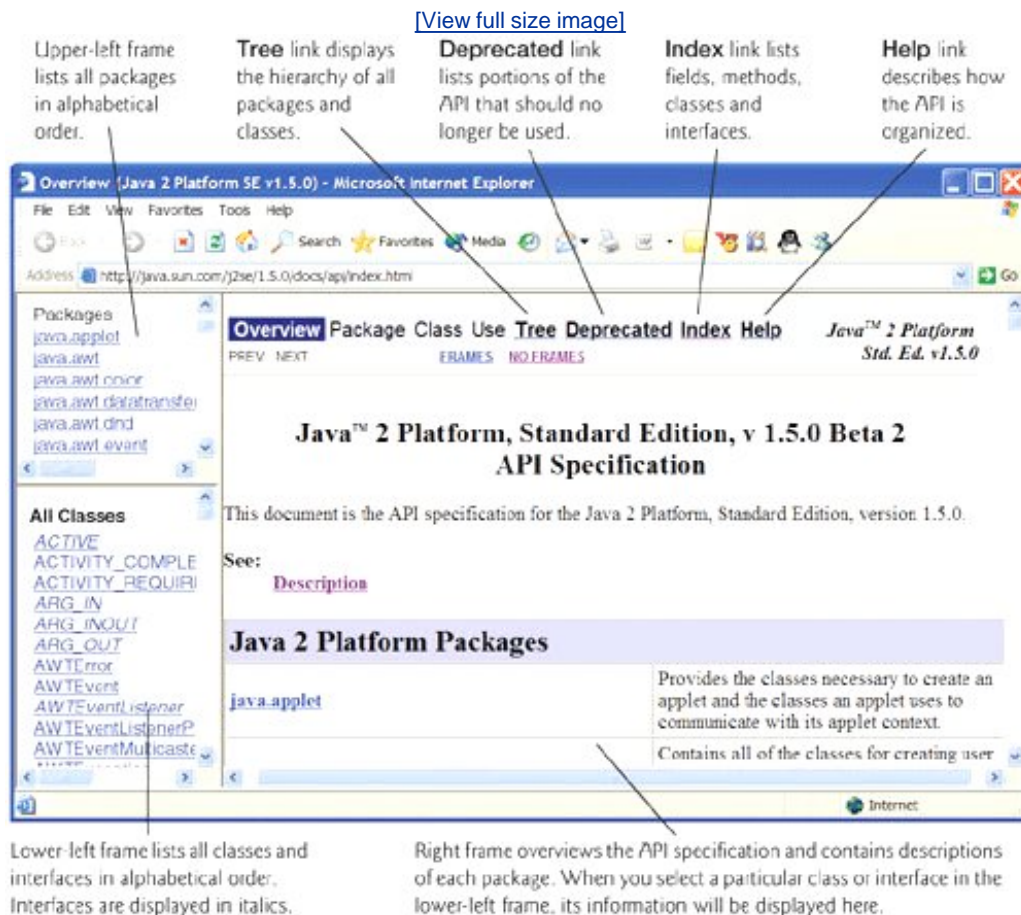

In addition, programmers often rely on the documentation to discover classes and interfaces that they have not used before. For this reason, we demonstrate the documentation with classes you know and classes you may not have studied yet. We show how to use the documentation to locate the information you need to use a class or interface effectively.

[*Note:* Sun Microsystems has renamed the Java 2 Platform, Standard Edition version 1.5.0 to Java 2 Platform, Standard Edition version 5.0. However, they decided not to replace the occurrences of 1.5.0 with 5.0 in the documentation. Although the URLs that represent the documentation on Sun's Java Web site work with 5.0 in the URL, these URLs are redirected to ones that replace the 5.0 with 1.5.0. For this reason, all URLs in this appendix are listed with 1.5.0 in the URL.]

## G.2. Navigating the Java API

The Java API documentation can be downloaded to your local hard disk or viewed on line. To download the Java API documentation, go to [java.sun.com/j2se/5.0/download.jsp](http://java.sun.com/j2se/5.0/download.jsp) and locate the **DOWNLOAD** link in the **J2SE v 1.5.0 Documentation** section. You will be asked to accept a license agreement. To do this, click **Accept**, then click **Continue**. Click the **Java(TM) 2 SDK, Standard Edition Documentation 1.5.0, English** link to begin the download. After downloading the file, you can use a ZIP file-extraction program, such as WinZip ([www.winzip.com](http://www.winzip.com)), to extract the files. If you are using Windows, extract the contents to your `jdk1.5.0` directory or the directory where you installed Java. (See the *Before You Begin* section of this book for information on installing Java.) To view the API documentation on your local hard disk in Microsoft Windows, open `C:\Program Files\Java\jdk1.5.0\docs\api\index.html` page in your browser. To view the API documentation on line, go to [java.sun.com/j2se/1.5.0/docs/api/index.html](http://java.sun.com/j2se/1.5.0/docs/api/index.html) (Fig. G.1).

Figure G.1. Java API overview. (Courtesy of Sun Microsystems, Inc.)

## Frames in the API Documentation's `index.html` Page

The API documentation is divided into three frames (see Fig. G.1). The upper-left frame lists all of the Java

API's packages in alphabetical order. The lower-left frame initially lists the Java API's classes and interfaces in alphabetical order. Interface names are displayed in italic. When you click a specific package in the upper-left frame, the lower-left frame lists the classes and interfaces of the selected package. The right frame initially provides a brief description of each package of the Java API specificationread this overview to become familiar with the general capabilities of the Java APIs. If you select a class or interface in the lower-left frame, the right frame displays information about that class or interface.

## Important Links in the `index.html` Page

At the top of the right frame ([Fig. G.1](#)), there are four links**Tree**, **Deprecated**, **Index** and **Help**. The **Tree** link displays the hierarchy of all packages, classes and interfaces in a tree structure. The **Deprecated** link displays interfaces, classes, exceptions, fields, constructors and methods that should no longer be used. The **Index** link displays classes, interfaces, fields, constructors and methods in alphabetical order. The **Help** link describes how the API documentation is organized. You should probably begin by reading the **Help** page.

## Viewing the Index Page

If you do not know the name of the class you are looking for, but you do know the name of a method or field, you can use the documentation's index to locate the class. The **Index** link is located near the upper-right corner of the right frame. The index page ([Fig. G.2](#)) displays fields, constructors, methods, interfaces and classes in alphabetical order. For example, if you are looking for `Scanner` method `hasNextInt`, but do not know the class name, you can click the **H** link to go to the alphabetical listing of all items in the Java API that begin with "h". Scroll to method `hasNextInt` ([Fig. G.3](#)). Once there, each method named `hasNextInt` is listed with the package name and class to which the method belongs. From there, you can click the class name to view the class's complete details, or you can click the method name to view the method's details.

---

[Page 1430]

Figure G.2. Viewing the **Index** page. (Courtesy of Sun Microsystems, Inc.)

(This item is displayed on page 1429 in the print version)

[\[View full size image\]](#)

Classes, interfaces and their members are listed in alphabetical order. Click a letter to view all fields, constructors, methods, interfaces and classes that start with that letter.

Click the **Index** link to display the documentation's index.

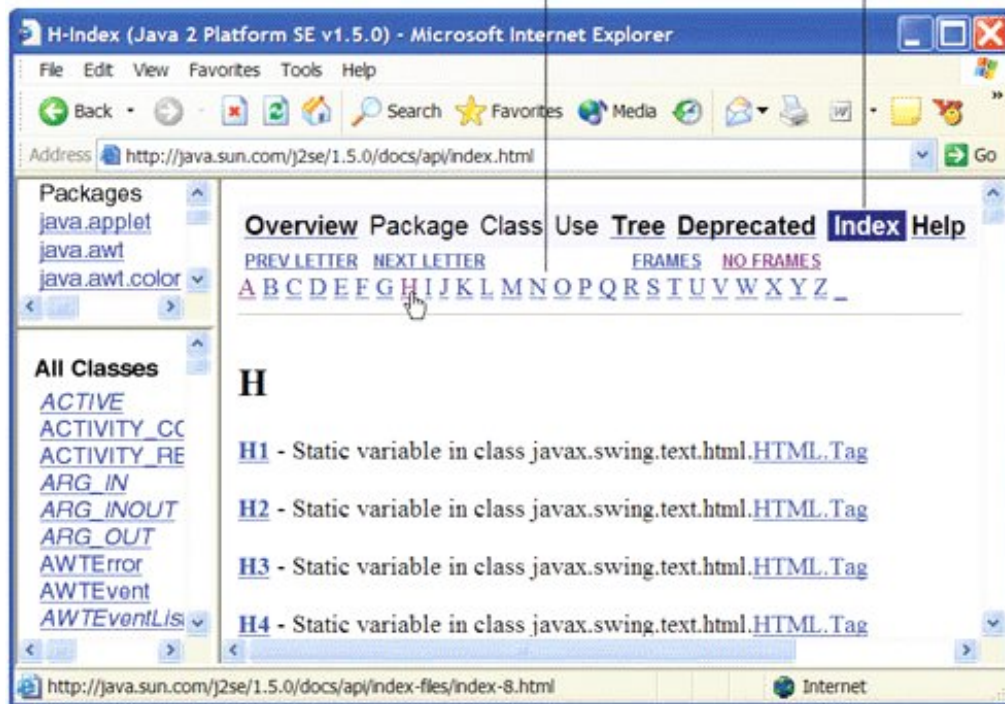

Figure G.3. Scroll to method `hasNextInt`. (Courtesy of Sun Microsystems, Inc.)

[\[View full size image\]](#)

Click the method name to view the method's details.

Click the class name to view the class's complete details.

## Viewing a Specific Package

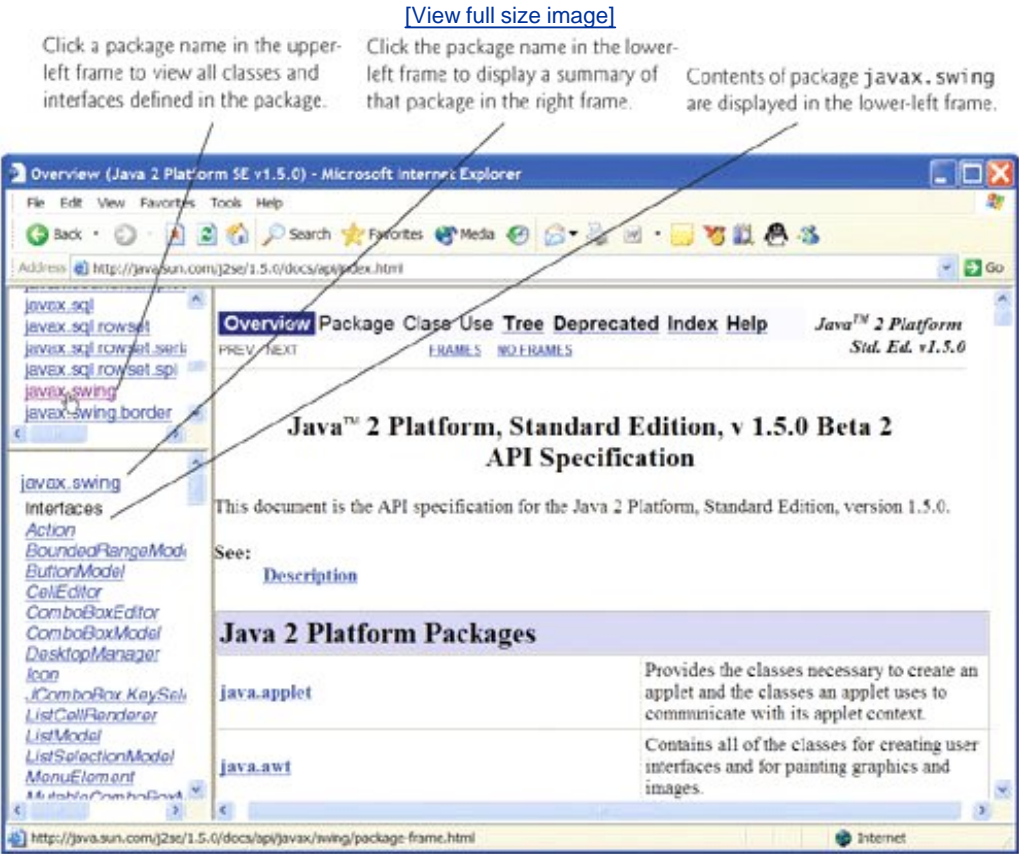

When you click the package name in the upper-left frame, all classes and interfaces from that package are displayed in the lower-left frame and are divided into five subsections: **Interfaces**, **Classes**, **Enums**, **Exceptions** and **Error** each listed alphabetically. For example, when you click `javax.swing` in the upper-left frame, the

contents of package `javax.swing` are displayed in the lower-left frame (Fig. G.4). You can click the package name in the lower-left frame to get an overview of the package. If you think that a package contains several classes that could be useful in your application, the package overview can be especially helpful.

Figure G.4. Clicking a package name in the upper-left frame to view all classes and interfaces declared in this package. (Courtesy of Sun Microsystems, Inc.)

(This item is displayed on page 1431 in the print version)

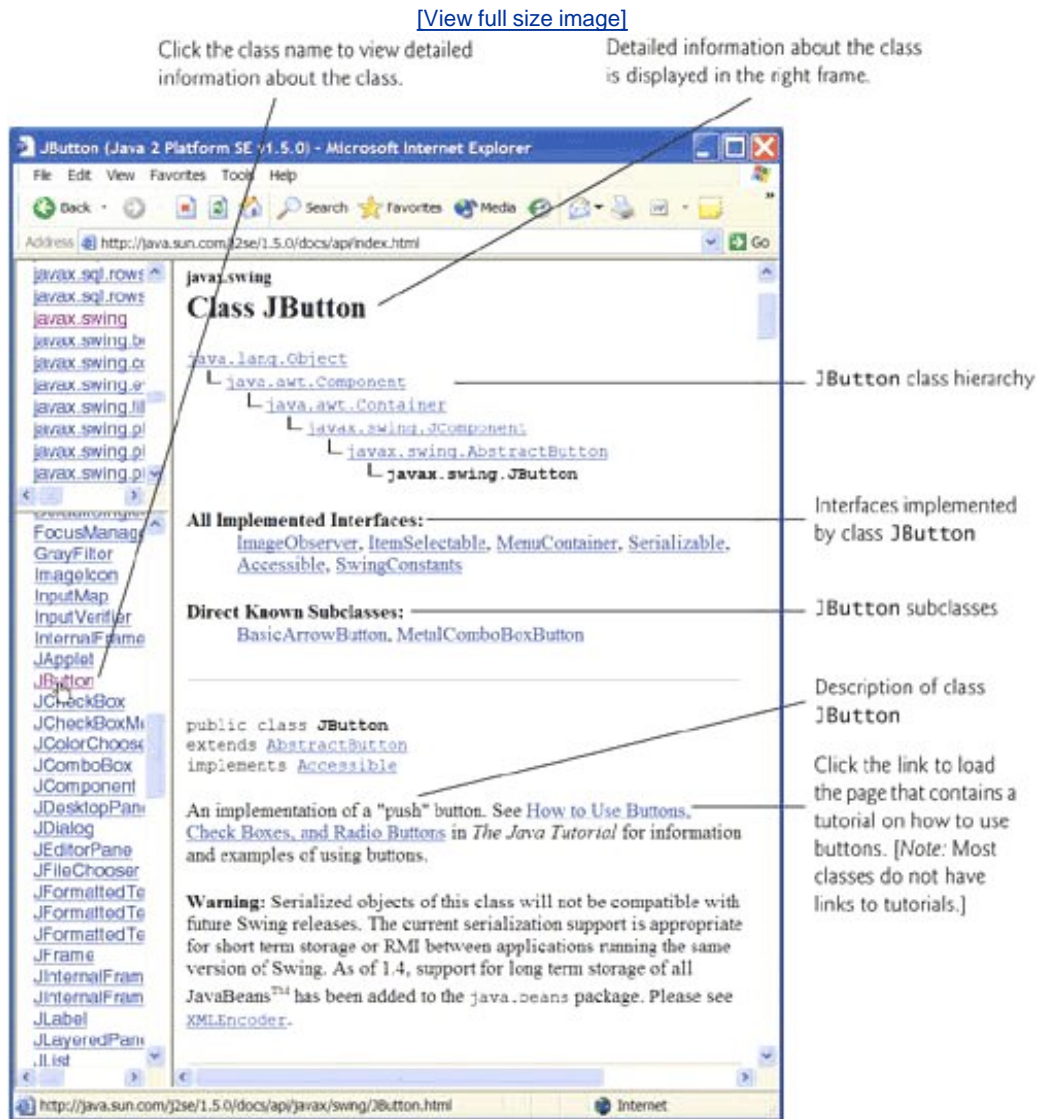

## Viewing the Details of a Class

When you click a class name or interface name in the lower-left frame, the right frame displays the details of that class or interface. First you will see the class's package name followed by a hierarchy that shows the class's relationship to other classes. You will also see a list of the interfaces implemented by the class and the class's known subclasses. Figure G.5 shows the beginning of the documentation page for class `JButton` from the `javax.swing` package. The page first shows the package name in which the class appears. This is followed by the class hierarchy that leads to class `JButton`, the interfaces class `JButton` implements and the subclasses of class `JButton`. The bottom of the right frame shows the beginning of class `JButton`'s description. Note that when you look at the documentation for an interface, the right frame does not display a hierarchy for that interface. Instead, the right frame lists the interface's superinterfaces, known subinterfaces and known implementing classes.

Figure G.5. Clicking a class name to view detailed information about the class. (Courtesy of Sun Microsystems, Inc.)

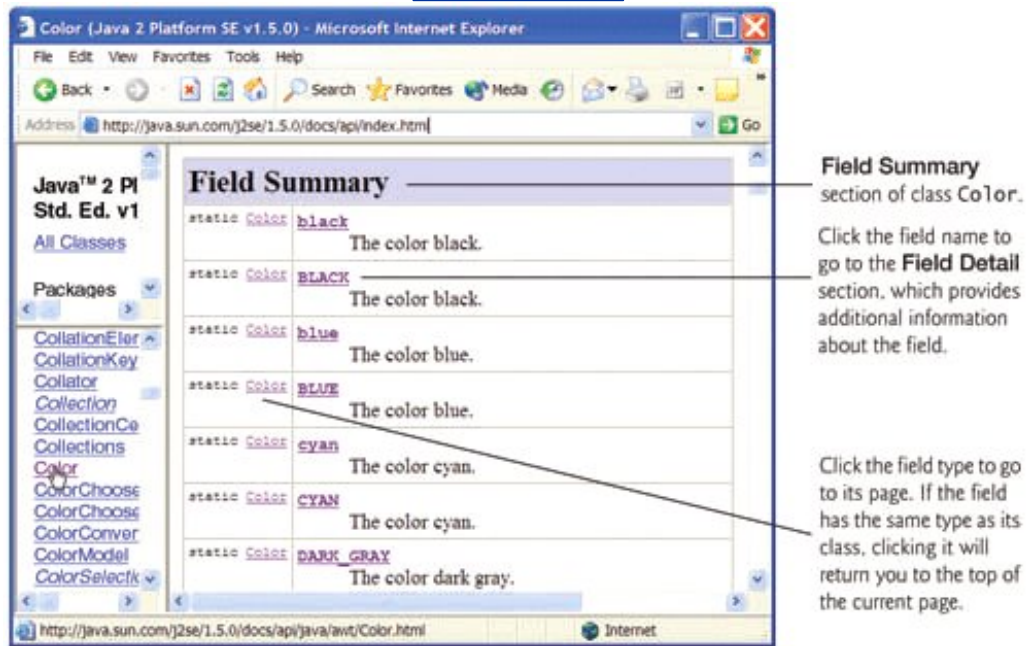

## Summary Sections in a Class's Documentation Page

Other parts of each API page are listed below. Each part is presented only if the class contains or inherits the items specified. Class members shown in the summary sections are **public** unless they are explicitly marked as **protected**. A class's **private** members are not shown in the documentation, because they cannot be used directly in your programs.

1. The **Nested Class Summary** section summarizes the class's **public** and **protected** nested classes, i.e., classes that are defined inside the class. Unless explicitly specified, these classes are **public** and **non-static**.
2. The **Field Summary** section summarizes the class's **public** and **protected** fields. Unless explicitly specified, these fields are **public** and **non-static**. [Figure G.6](#) shows the **Field Summary** section of class **Color**.

Figure G.6. **Field Summary** section of class **Color**. (Courtesy of Sun Microsystems, Inc.)

[\[View full size image\]](#)

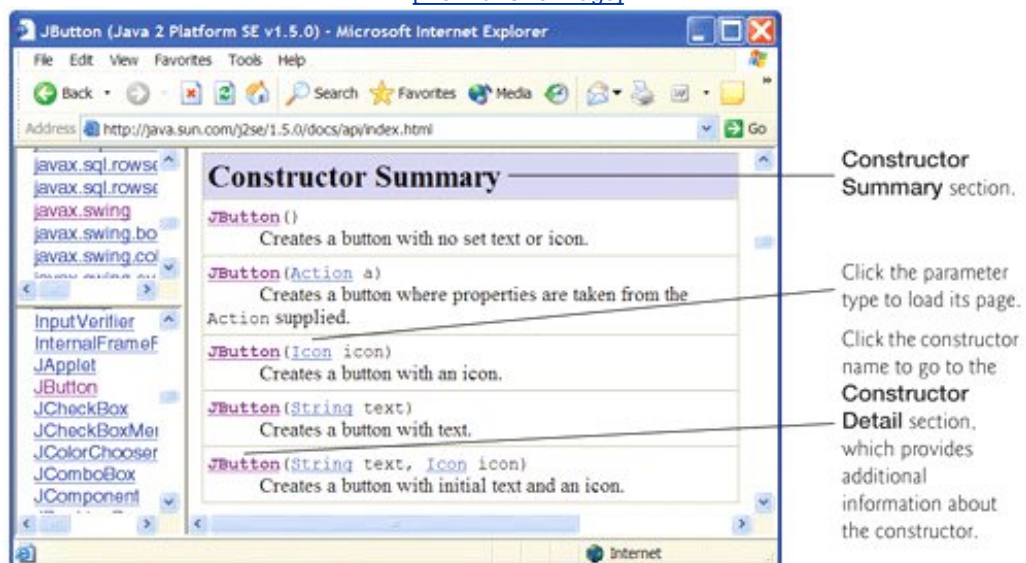

[Page 1432]

3. The **Constructor Summary** section summarizes the class's constructors. Constructors are not inherited, so this section appears in the documentation for a class only if the class declares one or more constructors. [Figure G.7](#) shows the **Constructor Summary** section of class `JButton`.

Figure G.7. **Constructor Summary** section of class `JButton`. (Courtesy of Sun Microsystems, Inc.)

[\[View full size image\]](#)

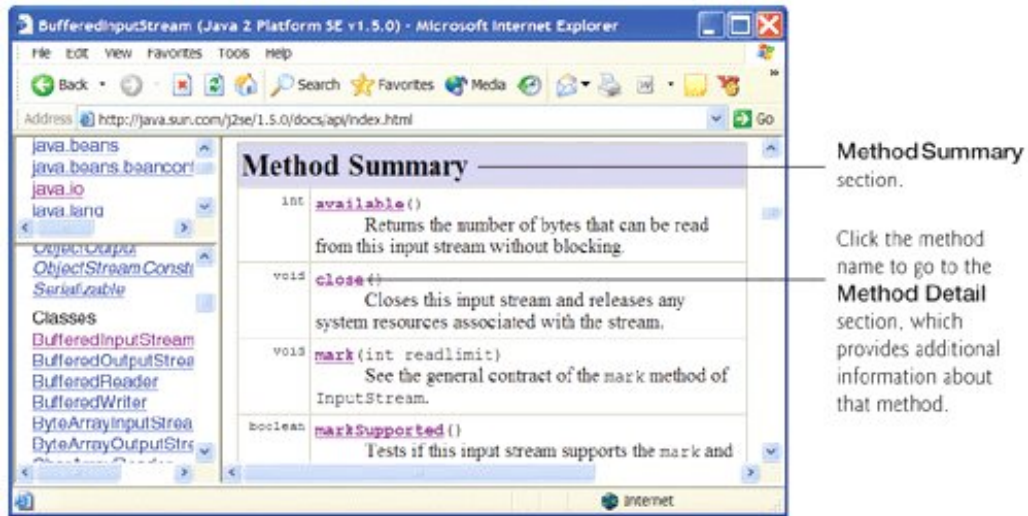

4. The **Method Summary** section summarizes the class's `public` and `protected` methods. Unless explicitly specified, these methods are `public` and non-`static`. [Figure G.8](#) shows the **Method Summary** section of class `BufferedInputStream`.

Figure G.8. **Method Summary** section of class **BufferedInputStream**. (Courtesy of Sun Microsystems, Inc.)

(This item is displayed on page 1434 in the print version)

[\[View full size image\]](#)

Note that the summary sections typically provide only a one-sentence description of a class member. Additional details are presented in the detail sections discussed next.

[Page 1434]

## Detail Sections in a Class's Documentation Page

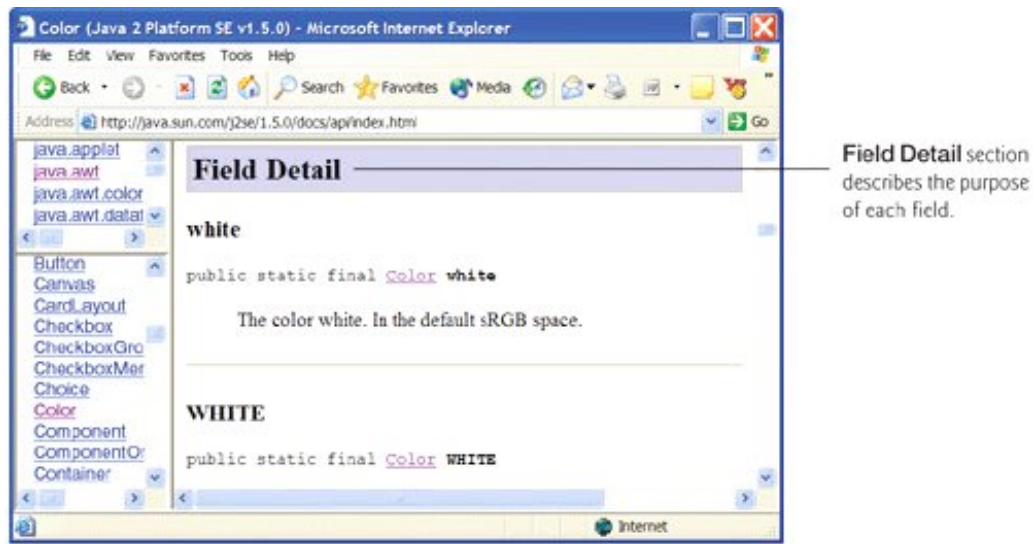

After the summary sections are detail sections that normally provide more discussion of particular class members. There is not a detail section for nested classes. When you click the link in the **Nested Class Summary** for a particular nested class, a documentation page describing that nested class is displayed. The detail sections are described below.

1. The **Field Detail** section provides the declaration of each field. It also discusses each field, including the field's modifiers and meaning. [Figure G.9](#) shows the **Field Detail** section of class `Color`.

Figure G.9. **Field Detail** section of class `Color`. (Courtesy of Sun Microsystems, Inc.)

(This item is displayed on page 1435 in the print version)

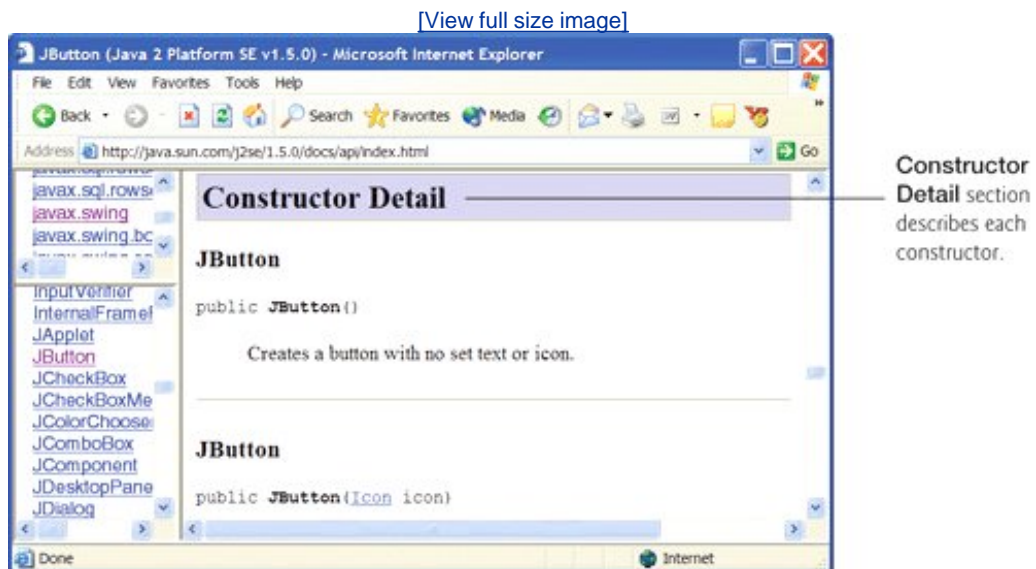

[\[View full size image\]](#)

2. The **Constructor Detail** section provides the first line of each constructor's declaration and discusses the constructors. The discussion includes the modifiers of each constructor, a description of each constructor, each constructor's parameters and any exceptions thrown by each constructor. [Figure G.10](#) shows the **Constructor Detail** section of class `JButton`.

Figure G.10. **Constructor Detail** section of class `JButton`. (Courtesy of Sun Microsystems, Inc.)

(This item is displayed on page 1435 in the print version)

3. The **Method Detail** section provides the first line of each method. The discussion of each method includes its modifiers, a more complete method description, the method's parameters, the method's return type and any exceptions thrown by the method. [Figure G.11](#) shows the **Method Detail** section of class `BufferedInputStream`. The method details show you other methods that might be of interest (labeled as **See Also**). If the method overrides a method of the superclass, the name of the superclass method and the name of the superclass are provided so you can link to the method or superclass for more information.

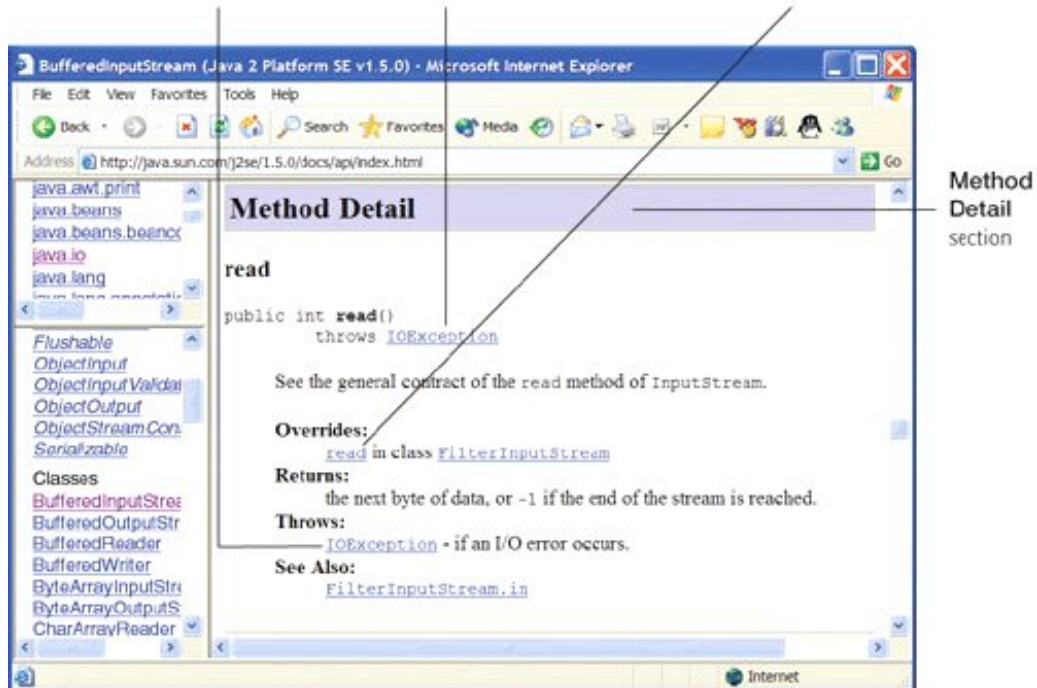

Figure G.11. **Method Detail** section of class `BufferedInputStream`. (Courtesy of Sun Microsystems, Inc.)

[\[View full size image\]](#)

Method `read` throws `IOException`. Click `IOException` to load the `IOException` class information page and learn more about the exception type (e.g., why such an exception might be thrown).

Method `read` overrides the `read` method in `FilterInputStream`. Click the name of the overridden method to view detailed information about the superclass's version of that method.

As you look through the documentation, you will notice that there are often links to other fields, methods, nested-classes and top-level classes. These links enable you to jump from the class you are looking at to another relevant portion of the documentation.

READ THE FOLLOWING TERMS AND CONDITIONS CAREFULLY BEFORE OPENING THIS SOFTWARE PACKAGE. THIS LEGAL DOCUMENT IS AN AGREEMENT BETWEEN YOU AND PRENTICE-HALL, INC. (THE "COMPANY"). BY OPENING THIS SEALED SOFTWARE PACKAGE, YOU ARE AGREEING TO BE BOUND BY THESE TERMS AND CONDITIONS. IF YOU DO NOT AGREE WITH THESE TERMS AND CONDITIONS, DO NOT OPEN THE SOFTWARE PACKAGE. PROMPTLY RETURN THE UNOPENED SOFTWARE PACKAGE AND ALL ACCOMPANYING ITEMS TO THE PLACE YOU OBTAINED THEM FOR A FULL REFUND OF ANY SUMS YOU HAVE PAID.

1. **GRANT OF LICENSE:** In consideration of your purchase of this book, and your agreement to abide by the terms and conditions of this Agreement, the Company grants to you a nonexclusive right to use and display the copy of the enclosed software program (hereinafter the "SOFTWARE") on a single computer (i.e., with a single CPU) at a single location so long as you comply with the terms of this Agreement. The Company reserves all rights not expressly granted to you under this Agreement.
2. **OWNERSHIP OF SOFTWARE:** You own only the magnetic or physical media (the enclosed media) on which the SOFTWARE is recorded or fixed, but the Company and the software developers retain all the rights, title, and ownership to the SOFTWARE recorded on the original media copy(ies) and all subsequent copies of the SOFTWARE, regardless of the form or media on which the original or other copies may exist. This license is not a sale of the original SOFTWARE or any copy to you.
3. **COPY RESTRICTIONS:** This SOFTWARE and the accompanying printed materials and user manual (the "Documentation") are the subject of copyright. The individual programs on the media are copyrighted by the authors of each program. Some of the programs on the media include separate licensing agreements. If you intend to use one of these programs, you must read and follow its accompanying license agreement. You may not copy the Documentation or the SOFTWARE, except that you may make a single copy of the SOFTWARE for backup or archival purposes only. You may be held legally responsible for any copying or copyright infringement which is caused or encouraged by your failure to abide by the terms of this restriction.
4. **USE RESTRICTIONS:** You may not network the SOFTWARE or otherwise use it on more than one computer or computer terminal at the same time. You may physically transfer the SOFTWARE from one computer to another provided that the SOFTWARE is used on only one computer at a time. You may not distribute copies of the SOFTWARE or Documentation to others. You may not reverse engineer, disassemble, decompile, modify, adapt, translate, or create derivative works based on the SOFTWARE or the Documentation without the prior written consent of the Company.
5. **TRANSFER RESTRICTIONS:** The enclosed SOFTWARE is licensed only to you and may not be transferred to any one else without the prior written consent of the Company. Any unauthorized transfer of the SOFTWARE shall result in the immediate termination of this Agreement.
6. **TERMINATION:** This license is effective until terminated. This license will terminate automatically without notice from the Company and become null and void if you fail to comply with any provisions or limitations of this license. Upon termination, you shall destroy the Documentation and all copies of the SOFTWARE. All provisions of this Agreement as to warranties, limitation of liability, remedies or damages, and our ownership rights shall survive termination.
7. **MISCELLANEOUS:** This Agreement shall be construed in accordance with the laws of the United States of America and the State of New York and shall benefit the Company, its affiliates, and assignees.
8. **LIMITED WARRANTY AND DISCLAIMER OF WARRANTY:** The Company warrants that the SOFTWARE, when properly used in accordance with the Documentation, will operate in substantial conformity with the description of the SOFTWARE set forth in the Documentation. The Company does not warrant that the SOFTWARE will meet your requirements or that the operation of the SOFTWARE will be uninterrupted or error-free. The Company warrants that the media on which the SOFTWARE is delivered shall be free from

defects in materials and workmanship under normal use for a period of thirty (30) days from the date of your purchase. Your only remedy and the Company's only obligation under these limited warranties is, at the Company's option, return of the warranted item for a refund of any amounts paid by you or replacement of the item. Any replacement of SOFTWARE or media under the warranties shall not extend the original warranty period. The limited warranty set forth above shall not apply to any SOFTWARE which the Company determines in good faith has been subject to misuse, neglect, improper installation, repair, alteration, or damage by you. EXCEPT FOR THE EXPRESSED WARRANTIES SET FORTH ABOVE, THE COMPANY DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. EXCEPT FOR THE EXPRESS WARRANTY SET FORTH ABOVE, THE COMPANY DOES NOT WARRANT, GUARANTEE, OR MAKE ANY REPRESENTATION REGARDING THE USE OR THE RESULTS OF THE USE OF THE SOFTWARE IN TERMS OF ITS CORRECTNESS, ACCURACY, RELIABILITY, CURRENTNESS, OR OTHERWISE.

---

[Page EULA-2]

IN NO EVENT, SHALL THE COMPANY OR ITS EMPLOYEES, AGENTS, SUPPLIERS, OR CONTRACTORS BE LIABLE FOR ANY INCIDENTAL, INDIRECT, SPECIAL, OR CONSEQUENTIAL DAMAGES ARISING OUT OF OR IN CONNECTION WITH THE LICENSE GRANTED UNDER THIS AGREEMENT, OR FOR LOSS OF USE, LOSS OF DATA, LOSS OF INCOME OR PROFIT, OR OTHER LOSSES, SUSTAINED AS A RESULT OF INJURY TO ANY PERSON, OR LOSS OF OR DAMAGE TO PROPERTY, OR CLAIMS OF THIRD PARTIES, EVEN IF THE COMPANY OR AN AUTHORIZED REPRESENTATIVE OF THE COMPANY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. IN NO EVENT SHALL LIABILITY OF THE COMPANY FOR DAMAGES WITH RESPECT TO THE SOFTWARE EXCEED THE AMOUNTS ACTUALLY PAID BY YOU, IF ANY, FOR THE SOFTWARE.

SOME JURISDICTIONS DO NOT ALLOW THE LIMITATION OF IMPLIED WARRANTIES OR LIABILITY FOR INCIDENTAL, INDIRECT, SPECIAL, OR CONSEQUENTIAL DAMAGES, SO THE ABOVE LIMITATIONS MAY NOT ALWAYS APPLY. THE WARRANTIES IN THIS AGREEMENT GIVE YOU SPECIFIC LEGAL RIGHTS AND YOU MAY ALSO HAVE OTHER RIGHTS WHICH VARY IN ACCORDANCE WITH LOCAL LAW.

ACKNOWLEDGMENT

YOU ACKNOWLEDGE THAT YOU HAVE READ THIS AGREEMENT, UNDERSTAND IT, AND AGREE TO BE BOUND BY ITS TERMS AND CONDITIONS. YOU ALSO AGREE THAT THIS AGREEMENT IS THE COMPLETE AND EXCLUSIVE STATEMENT OF THE AGREEMENT BETWEEN YOU AND THE COMPANY AND SUPERSEDES ALL PROPOSALS OR PRIOR AGREEMENTS, ORAL, OR WRITTEN, AND ANY OTHER COMMUNICATIONS BETWEEN YOU AND THE COMPANY OR ANY REPRESENTATIVE OF THE COMPANY RELATING TO THE SUBJECT MATTER OF THIS AGREEMENT.

Should you have any questions concerning this Agreement or if you wish to contact the Company for any reason, please contact in writing at the address below.

## TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

### 1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

---

[Page EULA-3]

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

## 2. Grant of Copyright License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

## 3. Grant of Patent License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

## 4. Redistribution

You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

- a. You must give any other recipients of the Work or Derivative Works a copy of this License; and
- b. You must cause any modified files to carry prominent notices stating that You changed the files; and
- c. You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
- d. If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

## 5. Submission of Contributions

Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

## 6. Trademarks

This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

## 7. Disclaimer of Warranty

Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

## 8. Limitation of Liability.

In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

## 9. Accepting Warranty or Additional Liability.

While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

## Appendix: How to apply the Apache License to your work

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

Licensed under the Apache License, Version 2.0 (the "License"); you may not use this file except in compliance with the License.

You may obtain a copy of the License at <http://www.apache.org/licenses/LICENSE-2.0>

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.

See the License for the specific language governing permissions and limitations under the License.

# JCreator™ License Agreement

END-USER LICENSE AGREEMENT FOR JCREATOR NOTICE TO ALL USERS: CAREFULLY READ THE FOLLOWING LEGAL AGREEMENT, FOR THE LICENSE OF SPECIFIED SOFTWARE BY XINOX SOFTWARE. BY INSTALLING THE SOFTWARE, YOU (EITHER AN INDIVIDUAL OR A SINGLE ENTITY) CONSENT TO BE BOUND BY AND BECOME A PARTY TO THIS AGREEMENT. IF YOU DO NOT AGREE TO ALL OF THE TERMS OF THIS AGREEMENT, CLICK THE BUTTON THAT INDICATES THAT YOU DO NOT ACCEPT THE TERMS OF THIS AGREEMENT AND DO NOT INSTALL THE SOFTWARE.

## 1. DEFINITIONS

- (a) "the Software" means the JCreator software program supplied by Xinox Software herewith, which may also include documentation, associated media, printed materials, and online and electronic documentation.
- (b) "User" means an individual end-user of the Software, being either faculty, staff, or an enrolled student in the case of a university or full-time staff in the case of a public institution or industrial firm.
- (c) "Licensee" is a User who has paid the license fee in full and who has been registered with Xinox Software.
- (d) "Xinox Software" or "Company" means Xinox Software and its suppliers and licensors, if any.
- (e) "Evaluation Period" means a version of the Software, so identified, to be used to review and evaluate the Software, only. See section 4.1 for more details.
- (f) "Private/Academic Version" means a version of the Software, so identified, for private(home) use or use by students and faculty of educational institutions, only. Private/Academic Versions may not be used for, or distributed to any party for, any commercial purpose. See section 4.2 for more details.

## 2. GENERAL

This End-User License Agreement ("EULA") is a legal agreement between you and Xinox Software for the Xinox Software products identified above, which may include computer software and associated media, electronic documentation and printed materials ("The Software"). By installing, copying, distributing or otherwise using The Software you agree to be bound by the terms of this EULA. If you do not agree to the terms of this EULA, you must not install, use or distribute The Software, and you must destroy all copies of The Software that you have. The Software is protected by copyright laws and international copyright treaties, as well as other intellectual property laws and treaties. The Software is licensed, not sold and always remains the property of Xinox Software.

Xinox Software will supply the Licensee with a single copy of the Software and Documents in electronic format, using a distribution mechanism decided on by Xinox Software. Xinox Software also will additionally supply the Licensee with a serial number and registration key. The Licensee agrees to restrict distribution of the registration key only to staff members with a need to know for purposes of configuring the Software or recording registration information for the usual business records of the Licensee, and will make all reasonable efforts to prevent duplication and any form of publication of the registration material.

If you have not paid the registration fee for the Software, you are hereby granted an evaluation license to use the Software as described in section 4.1.

## 3. LICENSE GRANT

Subject to the payment of the applicable license fees, and subject to the terms and conditions of this

Agreement, Xinox Software hereby grants to you a non-exclusive, non-transferable right to use the Software and the accompanying documentation (the "Documentation"). Except as set forth below, you may only install one copy of the Software on one computer, workstation or other electronic device for which the Software was designed (each, a "Client Device"). If the Software is licensed as a suite or bundle with more than one specified Software product, this license applies to all such specified Software products, subject to any restrictions or usage terms specified on the applicable price list or product packaging that apply to any of such Software products individually.

(a) Use. The Software is licensed as a single product; more than one user may not use it on more than one Client Device or at a time, except as set forth in this Section 3. The Software is "in use" on a Client Device when it is loaded into the temporary memory (i.e., random-access memory or RAM) or installed into the permanent memory (e.g., hard disk, CD-ROM, or other storage device) of that Client Device. This license authorizes you to make one copy of the Software solely for backup or archival purposes, provided that the copy you make contains all of the Software's proprietary notices.

(b) Multiple Client Devices. A licensed user is also granted a license to install the Software on more than one Client Device, for the sole use of that user.

(c) Server-Mode. You may use the Software on a Client Device as a server ("Server") within a multiuser or networked environment, on a single physical site, ("Server-Mode") only if such use is permitted in the applicable price list or product packaging for the Software. A separate license is required for each Client Device or "seat" that may connect to the Server at any time, regardless of whether such licensed Client Devices or seats are concurrently connected to, accessing or using the Software. Use of software or hardware that reduces the number of Client Devices or seats directly accessing or utilizing the Software (e.g., "multiplexing" or "pooling" software or hardware) does not reduce the number of licenses required (i.e., the required number of licenses would equal the number of distinct inputs to the multiplexing or pooling software or hardware "front end"). If the number of Client Devices or seats that can connect to the Software can exceed the number of licenses you have obtained, and then you must have a reasonable mechanism in place to ensure that your use of the Software does not exceed the use limits specified for the licenses you have obtained. This license authorizes you to make or download one copy of the Documentation for each Client Device or seat that is licensed, provided that each such copy contains all of the Documentation's proprietary notices.

---

[Page EULA-6]

(d) Volume Licenses. If the Software is licensed with volume license terms specified in the applicable price list or product packaging for the Software, you may make, use and install as many additional copies of the Software on the number of Client Devices as the volume license authorizes. You must have a reasonable mechanism in place to ensure that the number of Client Devices on which the Software has been installed does not exceed the number of licenses you have obtained. This license authorizes you to make or download one copy of the Documentation for each additional copy authorized by the volume license, provided that each such copy contains all of the Documentation's proprietary notices.

(e) Site Licenses. If the Software is licensed with site license terms, you may make, use and install unlimited copies of the Software within the organization site. This excludes Client Devices outside the organization, such as the home-computers of the students and staff members. This license authorizes you to make or download one copy of the Documentation for each copy authorized by the site license, provided that each such copy contains all of the Documentation's proprietary notices.

#### 4. LICENSE RESTRICTIONS

(a) Sublicense, sell, assign, transfer, pledge, distribute, rent or remove any proprietary notices on the Software except as expressly permitted in this Agreement.

(b) Use, copy, adapt, disassemble, decompile, reverse engineer or modify the Software, in whole or in part, except as expressly permitted in this Agreement.

(c) Take any action designed to unlock or bypass any Company-implemented restrictions on usage, access to, or number of installations of the Software; or.

(d) Use the Software if you fail to pay any license fee due and the Company notifies you that your license is

terminated.

(e) Disclose to third parties, or publish your registration details via electronic or other means.

IF YOU DO ANY OF THE FOREGOING, YOUR RIGHTS UNDER THIS LICENSE WILL AUTOMATICALLY TERMINATE. SUCH TERMINATION SHALL BE IN ADDITION TO AND NOT IN LIEU OF ANY CRIMINAL, CIVIL OR OTHER REMEDIES AVAILABLE TO XINOX SOFTWARE.

#### 4.1 RESTRICTED USE DURING EVALUATION PERIOD

You have a nonexclusive, nontransferable license to load and execute the unregistered copy of the Software for a period of thirty (30) days. (the "Evaluation Period"). The unregistered copy of the Software may be used for evaluation and testing purposes only and not for general commercial use. Customer must pay a license fee for the Software to obtain the right to use the Software for general commercial use and(or) for unlimited period. The unregistered copy of Software contains a feature that will automatically disable the Software in thirty (30) days. If you agree to this License Agreement and pay the license fee, Xinox Software will deactivate this feature. Xinox Software will have no liability to you if the Software is disabled by this feature. You may not disable, destroy, or remove this feature of the Software, and any attempt to do so will terminate your license and rights under this Agreement.

#### 4.2 RESTRICTED USE PRIVATE/ACADEMIC LICENSE

Subject to the terms of this EULA, use the Software for non-commercial purposes only including conducting academic research or providing educational services. You certify that use is directly related to teaching, private non-commercial development or that use is strictly for non-commercial research by students or and faculty members, where the results of such research or development are not intended primarily for the benefit of a third party. (The private/academic version contains the same methodology as the Professional Edition; the only difference is the license.)

#### 5. UPDATES

You are entitled to download revisions and upgrades (maintenance releases) to the Software as and when Xinox Software publishes it via its web site or through other online services. Xinox Software may charge an upgrade fee for new releases which contain significant enhancements.

#### 6. DISTRIBUTION

You are hereby licensed to make as many copies of the installation package for The Software as you wish; give exact copies of the original installation package for The Software to anyone; and distribute the original installation package for The Software in its unmodified form via electronic or other means. The Software must be clearly identified as a freeware or shareware version where described. You are specifically prohibited from charging, or requesting donations, for any such copies, however made; and from distributing The Software including documentation with other products (commercial or otherwise) without prior written permission from Xinox Software. You are also prohibited from distributing components of The Software other than the complete original installation package.

#### 7. OWNERSHIP

The foregoing license gives you limited license to use the Software. Xinox Software and its suppliers retain all right, title and interest, including all copyrights, in and to the Software and all copies thereof. All rights not specifically granted in this EULA, including Federal and International Copyrights, are reserved by Xinox Software and its suppliers. All title, including but not limited to copyrights, in and to The Software and any copies thereof are owned by Xinox Software. All title and intellectual property rights in and to the content which may be accessed through use of The Software is the property of the respective content owner and may be protected by applicable copyright or other intellectual property laws and treaties. This EULA grants you no rights to use such content. All rights not expressly granted are reserved by Xinox Software.

#### 8. WARRANTY AND DISCLAIMER

LIMITED WARRANTY TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, XINOX SOFTWARE DISCLAIMS ALL WARRANTIES AND CONDITIONS, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NON-INFRINGEMENT, WITH REGARD TO THE SOFTWARE, AND THE PROVISION OF OR FAILURE TO PROVIDE SUPPORT SERVICES. XINOX SOFTWARE DOES NOT WARRANT THAT THE SOFTWARE WILL MEET YOUR REQUIREMENTS OR THAT THE OPERATION OF THE SOFTWARE WILL BE UNINTERRUPTED OR ERROR FREE. THE ENTIRE RISK AS TO SATISFACTORY QUALITY, PERFORMANCE, ACCURACY, AND EFFORT IS WITH YOU, THE USER.

9. LIMITATION OF LIABILITY

LIMITATIONS OF REMEDIES AND LIABILITY TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT SHALL XINOX SOFTWARE BE LIABLE FOR ANY SPECIAL, INCIDENTAL, INDIRECT, CONSEQUENTIAL OR OTHER DAMAGES WHATSOEVER (INCLUDING, WITHOUT LIMITATION, DAMAGES FOR LOSS OF PROFITS, BUSINESS INTERRUPTION, LOSS OF INFORMATION, OR ANY OTHER PECUNIARY LOSS) ARISING OUT OF THE USE OF OR INABILITY TO USE THE SOFTWARE PRODUCT OR THE PROVISION OF OR FAILURE TO PROVIDE SUPPORT SERVICES, EVEN IF XINOX SOFTWARE HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. SOME STATES AND JURISDICTIONS DO NOT ALLOW THE EXCLUSION OR LIMITATION OF LIABILITY, THE ABOVE LIMITATION MAY NOT APPLY TO YOU.

10. HIGH RISK ACTIVITIES

The Software is not fault-tolerant and is not designed, manufactured or intended for use or resale as online control equipment in hazardous environments requiring fail-safe performance, such as in the operation of nuclear facilities, aircraft navigation or communication systems, air traffic control, direct life support machines, or weapons systems, in which the failure of the Software could lead directly to death, personal injury, or severe physical or environmental damage ("High Risk Activities"). Accordingly, Xinox Software and its suppliers and licensors specifically disclaim any express or implied warranty of fitness for High Risk Activities. You agree that Xinox Software and its suppliers and licensors will not be liable for any claims or damages arising from the use of the Software in such applications.

11. TERMINATION

Without prejudice to any other rights, Xinox Software may terminate this EULA if you fail to comply with the terms and conditions of this EULA. In such event, you must destroy all copies of The Software.

12. MISCELLANEOUS

This license is governed by Dutch Law and is subject to exclusive jurisdiction of the Dutch courts. This license constitutes the complete and exclusive statement of our agreement with you and supercedes all proposals, representations, understandings and prior agreements whether oral or written and all communications with you relating thereto.

# jEdit License Agreement

jEdit is released under the terms of the GNU General Public License, and developed by Slava Pestov and others.

## GNU General Public License

Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.

59 Temple Place - Suite 330, Boston, MA 02111-1307, USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

### Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software-- to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

---

[Page EULA-8]

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow. TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION 0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program";, below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

---

[Page EULA-9]

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

a) Accompany it with the complete corresponding machine-readable source code, which must be distributed

under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

## No Warranty

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

## END OF TERMS AND CONDITIONS

### How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

*one line to give the program's name and an idea of what it does.*  
*Copyright (C) yyyy name of author*

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of

---

[Page EULA-11]

MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  
See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 59 Temple Place - Suite 330, Boston, MA 02111-1307, USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

Gnomovision version 69, Copyright (C) year name of author  
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details  
type 'show w'. This is free software, and you are welcome  
to redistribute it under certain conditions; type 'show c'  
for details.

The hypothetical commands 'show w' and 'show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than 'show w' and 'show c'; they could even be mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright  
interest in the program 'Gnomovision'  
(which makes passes at compilers) written  
by James Hacker.

signature of Ty Coon, 1 April 1989  
Ty Coon, President of Vice

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

# jGRASP™ License Agreement

Software License for jGRASP Version 1.7.0

Copyright 1999-2004 Auburn University

## Section 1. License Grant.

Auburn University grants to you a non-exclusive and non-transferable license to use jGRASP and the associated documentation provided in jgrasp/help, collectively "jGRASP". jGRASP may be installed for use on a single computer or on a local area network. The "wedge" source code provided in the jgrasp/src directory is free of license restrictions. It may be used or modified for any purpose. jGRASP is a Trademark of Auburn University.

## Section 2. Restrictions

Distribution of jGRASP is not permitted without written permission (see Supplements), except that it may be distributed internally within a single organization. Distribution of components of jGRASP separately from the whole is not permitted, except that the complete associated documentation provided in jgrasp/help may be distributed separately. Reverse engineering of jGRASP is not permitted. Any use of image files, icons, or executable components of jGRASP separately from the whole is prohibited.

## Section 3. Disclaimer of Warranty

jGRASP is licensed "as is". There are no express or implied warranties, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. Auburn University makes no warranty with respect to the accuracy or completeness of information obtained through the use of this program. Auburn University does not warrant that jGRASP will meet all of your requirements or that its operation will be uninterrupted or error free or that any defect within jGRASP will be corrected. No oral or written information, representation, or advice given by Auburn University or an authorized representative of Auburn University shall create a warranty. Auburn University and its agents shall in no event be held liable to the user for any damages, including direct, indirect, incidental, or consequential damages, lost profits, lost savings, or other such damages arising out of the installation, use, improper use, or inability to use jGRASP, even if Auburn University has been advised of the possibility of such damages, or any claim by any other person or entity related thereto.

## Supplements

Distribution for Educational Purposes - Publishers may distribute the jGRASP software and the jGRASP Handbook (Tutorials and Reference) on CDs that accompany their textbooks provided that (1) the title "jGRASP(TM) 1.7.0 copyright 1999-2004 Auburn University" is included on each CD label, (2) descriptions of the CD indicate that jGRASP is included on the CD, and (3) a list of the textbooks that include jGRASP is provided to Auburn University (crossATengDOTauburnDOTedu). Permission to distribute jGRASP for educational purposes covers all CDs created prior to December 31, 2004 for inclusion in textbooks. While it is anticipated that distribution of jGRASP for educational purposes will remain royalty free, this supplement of the jGRASP license will be re-evaluated on an annual basis.

For additional information, contact James H. Cross II, Computer Science and Software Engineering, 107 Dunstan Hall, Auburn University, AL 36849 (334-844-6315, crossATengDOTauburnDOTedu).

# NetBeans™ License Agreement

Netbeans IDE and Netbeans Platform are based on software from [netbeans.org](http://netbeans.org), developed under Sun Public License (SPL). For more information visit [www.netbeans.org](http://www.netbeans.org).

## SUN PUBLIC LICENSE

### SUN PUBLIC LICENSE Version 1.0

1.0.1. "Commercial Use" means distribution or otherwise making the Covered Code available to a third party.

1.1. "Contributor" means each entity that creates or contributes to the creation of Modifications.

1.2. "Contributor Version" means the combination of the Original Code, prior Modifications used by a Contributor, and the Modifications made by that particular Contributor.

1.3. "Covered Code" means the Original Code or Modifications or the combination of the Original Code and Modifications, in each case including portions thereof and corresponding documentation released with the source code.

1.4. "Electronic Distribution Mechanism" means a mechanism generally accepted in the software development community for the electronic transfer of data.

1.5. "Executable" means Covered Code in any form other than Source Code.

1.6. "Initial Developer" means the individual or entity identified as the Initial Developer in the Source Code notice required by Exhibit A.

1.7. "Larger Work" means a work which combines Covered Code or portions thereof with code not governed by the terms of this License.

1.8. "License" means this document.

1.8.1. "Licensable" means having the right to grant, to the maximum extent possible, whether at the time of the initial grant or subsequently acquired, any and all of the rights conveyed herein.

1.9. "Modifications" means any addition to or deletion from the substance or structure of either the Original Code or any previous Modifications. When Covered Code is released as a series of files, a Modification is:

A. Any addition to or deletion from the contents of a file containing Original Code or previous Modifications.

B. Any new file that contains any part of the Original Code or previous Modifications.

1.10. "Original Code" means Source Code of computer software code which is described in the Source Code notice required by Exhibit A as Original Code, and which, at the time of its release under this License is not already Covered Code governed by this License.

1.10.1. "Patent Claims" means any patent claim(s), now owned or hereafter acquired, including without limitation, method, process, and apparatus claims, in any patent Licensable by grantor.

1.11. "Source Code" means the preferred form of the Covered Code for making modifications to it, including all modules it contains, plus any associated documentation, interface definition files, scripts used to control compilation and installation of an Executable, or source code differential comparisons against either the

Original Code or another well known, available Covered Code of the Contributor's choice. The Source Code can be in a compressed or archival form, provided the appropriate decompression or de-archiving software is widely available for no charge.

1.12. "You" (or "Your") means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License or a future version of this License issued under section 6.1. For legal entities, "You" includes any entity which controls, is controlled by, or is under common control with You. For purposes of this definition, "control" means (a) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (b) ownership of more than fifty percent (50%) of the outstanding shares or beneficial ownership of such entity.

## 2. Source Code License.

### 2.1 The Initial Developer Grant.

The Initial Developer hereby grants You a world-wide, royalty-free, non-exclusive license, subject to third party intellectual property claims:

(a) under intellectual property rights (other than patent or trademark) Licensable by Initial Developer to use, reproduce, modify, display, perform, sublicense and distribute the Original Code (or portions thereof) with or without Modifications, and/or as part of a Larger Work; and

(b) under Patent Claims infringed by the making, using or selling of Original Code, to make, have made, use, practice, sell, and offer for sale, and/or otherwise dispose of the Original Code (or portions thereof).

(c) the licenses granted in this Section 2.1(a) and (b) are effective on the date Initial Developer first distributes Original Code under the terms of this License.

(d) Notwithstanding Section 2.1(b) above, no patent license is granted: 1) for code that You delete from the Original Code; 2) separate from the Original Code; or 3) for infringements caused by: i) the modification of the Original Code or ii) the combination of the Original Code with other software or devices.

### 2.2. Contributor Grant.

Subject to third party intellectual property claims, each Contributor hereby grants You a world-wide, royalty-free, non-exclusive license

(a) under intellectual property rights (other than patent or trademark) Licensable by Contributor, to use, reproduce, modify, display, perform, sublicense and distribute the Modifications created by such Contributor (or portions thereof) either on an unmodified basis, with other Modifications, as Covered Code and/or as part of a Larger Work; and

(b) under Patent Claims infringed by the making, using, or selling of Modifications made by that Contributor either alone and/or in combination with its Contributor Version (or portions of such combination), to make, use, sell, offer for sale, have made, and/or otherwise dispose of: 1) Modifications made by that Contributor (or portions thereof); and 2) the combination of Modifications made by that Contributor with its Contributor Version (or portions of such combination).

(c) the licenses granted in Sections 2.2(a) and 2.2(b) are effective on the date Contributor first makes Commercial Use of the Covered Code.

(d) notwithstanding Section 2.2(b) above, no patent license is granted: 1) for any code that Contributor has deleted from the Contributor Version; 2) separate from the Contributor Version; 3) for infringements caused by: i) third party modifications of Contributor Version or ii) the combination of Modifications made by that Contributor with other software (except as part of the Contributor Version) or other devices; or 4) under Patent Claims infringed by Covered Code in the absence of Modifications made by that Contributor.

## 3. Distribution Obligations.

### 3.1. Application of License.

The Modifications which You create or to which You contribute are governed by the terms of this License, including without limitation Section 2.2. The Source Code version of Covered Code may be distributed only under the terms of this License or a future version of this License released under section 6.1, and You must include a copy of this License with every copy of the Source Code You distribute. You may not offer or impose any terms on any Source Code version that alters or restricts the applicable version of this License or the recipients' rights hereunder. However, You may include an additional document offering the additional rights described in Section 3.5.

### 3.2. Availability of Source Code.

Any Modification which You create or to which You contribute must be made available in Source Code form under the terms of this License either on the same media as an Executable version or via an accepted Electronic Distribution Mechanism to anyone to whom you made an Executable version available; and if made available via Electronic Distribution Mechanism, must remain available for at least twelve (12) months after the date it initially became available, or at least six (6) months after a subsequent version of that particular Modification has been made available to such recipients. You are responsible for ensuring that the Source Code version remains available even if the Electronic Distribution Mechanism is maintained by a third party.

### 3.3. Description of Modifications.

You must cause all Covered Code to which You contribute to contain a file documenting the changes You made to create that Covered Code and the date of any change. You must include a prominent statement that the Modification is derived, directly or indirectly, from Original Code provided by the Initial Developer and including the name of the Initial Developer in (a) the Source Code, and (b) in any notice in an Executable version or related documentation in which You describe the origin or ownership of the Covered Code.

### 3.4. Intellectual Property Matters.

#### (a) Third Party Claims.

If Contributor has knowledge that a license under a third party's intellectual property rights is required to exercise the rights granted by such Contributor under Sections 2.1 or 2.2, Contributor must include a text file with the Source Code distribution titled "LEGAL" which describes the claim and the party making the claim in sufficient detail that a recipient will know whom to contact. If Contributor obtains such knowledge after the Modification is made available as described in Section 3.2, Contributor shall promptly modify the LEGAL file in all copies Contributor makes available thereafter and shall take other steps (such as notifying appropriate mailing lists or newsgroups) reasonably calculated to inform those who received the Covered Code that new knowledge has been obtained.

#### (b) Contributor APIs.

If Contributor's Modifications include an application programming interface ("API") and Contributor has knowledge of patent licenses which are reasonably necessary to implement that API, Contributor must also include this information in the LEGAL file.

#### (c) Representations.

Contributor represents that, except as disclosed pursuant to Section 3.4(a) above, Contributor believes that Contributor's Modifications are Contributor's original creation(s) and/or Contributor has sufficient rights to grant the rights conveyed by this License.

### 3.5. Required Notices.

You must duplicate the notice in Exhibit A in each file of the Source Code. If it is not possible to put such notice in a particular Source Code file due to its structure, then You must include such notice in a location (such as a relevant directory) where a user would be likely to look for such a notice. If You created one or more Modification(s) You may add your name as a Contributor to the notice described in Exhibit A. You must also duplicate this License in any documentation for the Source Code where You describe recipients' rights or ownership rights relating to Covered Code. You may choose to offer, and to charge a fee for, warranty, support, indemnity or liability obligations to one or more recipients of Covered Code. However, You may do

so only on Your own behalf, and not on behalf of the Initial Developer or any Contributor. You must make it absolutely clear than any such warranty, support, indemnity or liability obligation is offered by You alone, and You hereby agree to indemnify the Initial Developer and every Contributor for any liability incurred by the Initial Developer or such Contributor as a result of warranty, support, indemnity or liability terms You offer.

### 3.6. Distribution of Executable Versions.

You may distribute Covered Code in Executable form only if the requirements of Section 3.1-3.5 have been met for that Covered Code, and if You include a notice stating that the Source Code version of the Covered Code is available under the terms of this License, including a description of how and where You have fulfilled the obligations of Section 3.2. The notice must be conspicuously included in any notice in an Executable version, related documentation or collateral in which You describe recipients' rights relating to the Covered Code. You may distribute the Executable version of Covered Code or ownership rights under a license of Your choice, which may contain terms different from this License, provided that You are in compliance with the terms of this License and that the license for the Executable version does not attempt to limit or alter the recipient's rights in the Source Code version from the rights set forth in this License. If You distribute the Executable version under a different license You must make it absolutely clear that any terms which differ from this License are offered by You alone, not by the Initial Developer or any Contributor. You hereby agree to indemnify the Initial Developer and every Contributor for any liability incurred by the Initial Developer or such Contributor as a result of any such terms You offer.

---

[Page EULA-15]

### 3.7. Larger Works.

You may create a Larger Work by combining Covered Code with other code not governed by the terms of this License and distribute the Larger Work as a single product. In such a case, You must make sure the requirements of this License are fulfilled for the Covered Code.

## 4. Inability to Comply Due to Statute or Regulation.

If it is impossible for You to comply with any of the terms of this License with respect to some or all of the Covered Code due to statute, judicial order, or regulation then You must: (a) comply with the terms of this License to the maximum extent possible; and (b) describe the limitations and the code they affect. Such description must be included in the LEGAL file described in Section 3.4 and must be included with all distributions of the Source Code. Except to the extent prohibited by statute or regulation, such description must be sufficiently detailed for a recipient of ordinary skill to be able to understand it.

## 5. Application of this License.

This License applies to code to which the Initial Developer has attached the notice in Exhibit A and to related Covered Code.

## 6. Versions of the License.

### 6.1. New Versions.

Sun Microsystems, Inc. ("Sun") may publish revised and/or new versions of the License from time to time. Each version will be given a distinguishing version number.

### 6.2. Effect of New Versions.

Once Covered Code has been published under a particular version of the License, You may always continue to use it under the terms of that version. You may also choose to use such Covered Code under the terms of any subsequent version of the License published by Sun. No one other than Sun has the right to modify the terms applicable to Covered Code created under this License.

### 6.3. Derivative Works.

If You create or use a modified version of this License (which you may only do in order to apply it to code

which is not already Covered Code governed by this License), You must: (a) rename Your license so that the phrases "Sun," "Sun Public License," or "SPL" or any confusingly similar phrase do not appear in your license (except to note that your license differs from this License) and (b) otherwise make it clear that Your version of the license contains terms which differ from the Sun Public License. (Filling in the name of the Initial Developer, Original Code or Contributor in the notice described in Exhibit A shall not of themselves be deemed to be modifications of this License.)

## 7. DISCLAIMER OF WARRANTY.

COVERED CODE IS PROVIDED UNDER THIS LICENSE ON AN "AS IS" BASIS, WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, WITHOUT LIMITATION, WARRANTIES THAT THE COVERED CODE IS FREE OF DEFECTS, MERCHANTABLE, FIT FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE COVERED CODE IS WITH YOU. SHOULD ANY COVERED CODE PROVE DEFECTIVE IN ANY RESPECT, YOU (NOT THE INITIAL DEVELOPER OR ANY OTHER CONTRIBUTOR) ASSUME THE COST OF ANY NECESSARY SERVICING, REPAIR OR CORRECTION. THIS DISCLAIMER OF WARRANTY CONSTITUTES AN ESSENTIAL PART OF THIS LICENSE. NO USE OF ANY COVERED CODE IS AUTHORIZED HEREUNDER EXCEPT UNDER THIS DISCLAIMER.

## 8. TERMINATION.

8.1. This License and the rights granted hereunder will terminate automatically if You fail to comply with terms herein and fail to cure such breach within 30 days of becoming aware of the breach. All sublicenses to the Covered Code which are properly granted shall survive any termination of this License. Provisions which, by their nature, must remain in effect beyond the termination of this License shall survive.

8.2. If You initiate litigation by asserting a patent infringement claim (excluding declaratory judgment actions) against Initial Developer or a Contributor (the Initial Developer or Contributor against whom You file such action is referred to as "Participant") alleging that:

---

(a) such Participant's Contributor Version directly or indirectly infringes any patent, then any and all rights granted by such Participant to You under Sections 2.1 and/or 2.2 of this License shall, upon 60 days notice from Participant terminate prospectively, unless if within 60 days after receipt of notice You either: (i) agree in writing to pay Participant a mutually agreeable reasonable royalty for Your past and future use of Modifications made by such Participant, or (ii) withdraw Your litigation claim with respect to the Contributor Version against such Participant. If within 60 days of notice, a reasonable royalty and payment arrangement are not mutually agreed upon in writing by the parties or the litigation claim is not withdrawn, the rights granted by Participant to You under Sections 2.1 and/or 2.2 automatically terminate at the expiration of the 60 day notice period specified above.

(b) any software, hardware, or device, other than such Participant's Contributor Version, directly or indirectly infringes any patent, then any rights granted to You by such Participant under Sections 2.1(b) and 2.2(b) are revoked effective as of the date You first made, used, sold, distributed, or had made, Modifications made by that Participant.

8.3. If You assert a patent infringement claim against Participant alleging that such Participant's Contributor Version directly or indirectly infringes any patent where such claim is resolved (such as by license or settlement) prior to the initiation of patent infringement litigation, then the reasonable value of the licenses granted by such Participant under Sections 2.1 or 2.2 shall be taken into account in determining the amount or value of any payment or license.

8.4. In the event of termination under Sections 8.1 or 8.2 above, all end user license agreements (excluding distributors and resellers) which have been validly granted by You or any distributor hereunder prior to termination shall survive termination.

## 9. LIMITATION OF LIABILITY.

UNDER NO CIRCUMSTANCES AND UNDER NO LEGAL THEORY, WHETHER TORT (INCLUDING NEGLIGENCE), CONTRACT, OR OTHERWISE, SHALL YOU, THE INITIAL DEVELOPER, ANY OTHER CONTRIBUTOR, OR ANY DISTRIBUTOR OF COVERED CODE, OR ANY SUPPLIER OF ANY OF SUCH PARTIES, BE LIABLE TO ANY

PERSON FOR ANY INDIRECT, SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES OF ANY CHARACTER INCLUDING, WITHOUT LIMITATION, DAMAGES FOR LOSS OF GOODWILL, WORK STOPPAGE, COMPUTER FAILURE OR MALFUNCTION, OR ANY AND ALL OTHER COMMERCIAL DAMAGES OR LOSSES, EVEN IF SUCH PARTY SHALL HAVE BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. THIS LIMITATION OF LIABILITY SHALL NOT APPLY TO LIABILITY FOR DEATH OR PERSONAL INJURY RESULTING FROM SUCH PARTY'S NEGLIGENCE TO THE EXTENT APPLICABLE LAW PROHIBITS SUCH LIMITATION. SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OR LIMITATION OF INCIDENTAL OR CONSEQUENTIAL DAMAGES, SO THIS EXCLUSION AND LIMITATION MAY NOT APPLY TO YOU.

10. U.S. GOVERNMENT END USERS.

The Covered Code is a "commercial item," as that term is defined in 48 C.F.R. 2.101 (Oct. 1995), consisting of "commercial computer software" and "commercial computer software documentation," as such terms are used in 48 C.F.R. 12.212 (Sept. 1995). Consistent with 48 C.F.R. 12.212 and 48 C.F.R. 227.7202-1 through 227.7202-4 (June 1995), all U.S. Government End Users acquire Covered Code with only those rights set forth herein.

11. MISCELLANEOUS.

This License represents the complete agreement concerning subject matter hereof. If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable. This License shall be governed by California law provisions (except to the extent applicable law, if any, provides otherwise), excluding its conflict-of-law provisions. With respect to disputes in which at least one party is a citizen of, or an entity chartered or registered to do business in the United States of America, any litigation relating to this License shall be subject to the jurisdiction of the Federal Courts of the Northern District of California, with venue lying in Santa Clara County, California, with the losing party responsible for costs, including without limitation, court costs and reasonable attorneys' fees and expenses. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any law or regulation which provides that the language of a contract shall be construed against the drafter shall not apply to this License.

12. RESPONSIBILITY FOR CLAIMS.

As between Initial Developer and the Contributors, each party is responsible for claims and damages arising, directly or indirectly, out of its utilization of rights under this License and You agree to work with Initial Developer and Contributors to distribute such responsibility on an equitable basis. Nothing herein is intended or shall be deemed to constitute any admission of liability.

13. MULTIPLE-LICENSED CODE.

Initial Developer may designate portions of the Covered Code as "Multiple-Licensed". "Multiple-Licensed" means that the Initial Developer permits you to utilize portions of the Covered Code under Your choice of the alternative licenses, if any, specified by the Initial Developer in the file described in Exhibit A.

Exhibit A -Sun Public License Notice.

The contents of this file are subject to the Sun Public License Version 1.0 (the "License"); you may not use this file except in compliance with the License. A copy of the License is available at <http://www.sun.com/>

The Original Code is \_\_\_\_\_. The Initial Developer of the Original Code is \_\_\_\_\_.

Portions created by \_\_\_\_\_ are Copyright(C) \_\_\_\_\_. All Rights Reserved.

Contributor(s): \_\_\_\_\_.

Alternatively, the contents of this file may be used under the terms of the \_\_\_\_\_ license (the "[\_\_\_\_\_]" License), in which case the provisions of [\_\_\_\_\_] License are applicable instead of those above. If you wish to allow use of your version of this file only under the terms of the [\_\_\_\_\_] License and not to allow others to use your version of this file under the SPL, indicate your decision by

deleting the provisions above and replace them with the notice and other provisions required by the [\_\_\_\_\_] License. If you do not delete the provisions above, a recipient may use your version of this file under either the SPL or the [\_\_\_\_\_] License."

*[NOTE: The text of this Exhibit A may differ slightly from the text of the notices in the Source Code files of the Original Code. You should use the text of this Exhibit A rather than the text found in the Original Code Source Code for Your Modifications.]*

**NEXT** 

# MySQL® Open Source License

Our software is 100% GPL (General Public License); if yours is 100% GPL compliant, then you have no obligation to pay us for the licenses. This is a great opportunity for the open source community and those of you who are developing open source software.

The formal terms of the GPL license can be found in the GNU General Public License section of the MySQL Reference Manual. Please note that the General Public License can be restrictive, so if it doesn't meet your needs, you are better served by our Commercial License.

Specifically:

- MySQL is free use for those who are 100%GPL. If your application is licensed under GPL or compatible OSI license approved by MySQL AB, you are free to ship any GPL software of MySQL AB with your application ('application' means any type of software application, system, tool or utility). You do not need a separate signed agreement with MySQL AB, because the GPL license is sufficient. We do, however, recommend you contact us as there usually are good opportunities for partnership and co-marketing.
- Under the Open Source License, you must release the complete source code for the application that is built on MySQL. You do not need to release the source code for components that are generally installed on the operating system on which your application runs, such as system header files or libraries.
- Free use for those who never copy, modify or distribute. As long as you never distribute (internally or externally) the MySQL Software in any way, you are free to use it for powering your application, irrespective of whether your application is under GPL license or not.
- You are allowed to modify MySQL Software source code any way you like as long as the distributed derivative work is licensed under the GPL as well.
- You are allowed to copy MySQL binaries and source code, but when you do so, the copies will fall under the GPL license.
- Optional GPL License Exception for PHP. As a special exception, MySQL AB gives permission to distribute derivative works that are formed with GPL-licensed MySQL software and with software licensed under version 3.0 of the PHP license. You must obey the GNU General Public License in all respects for all of the code used other than code licensed under version 3.0 of the PHP license.
- FOSS Exception. We have created a which enables Free and Open Source software ("FOSS") to be able to include the GPL-licensed MySQL client libraries despite the fact that not all open source licenses are compatible with the GPL.

## Non-Profits, Academic Institutions, and Private Individuals

If you represent a non-profit organization or an academic institution, we recommend you publish your application as an open source / free software project using the GPL license. Thereby, you are free to use MySQL software free of charge under the GPL license. We believe that if you have strong reasons to not publish your application in accordance with the GPL, you should purchase commercial licenses. Note that non-profits can apply for free commercial licenses, which will be liberally granted.

If you are a private individual you are free to use MySQL software for your personal applications as long as you do not distribute them. If you distribute them, you must make a decision between the Commercial License and the GPL.

Please note that even if you ship a free demo version of your own application, the above rules apply.

## Recommendations

Please note that MySQL AB can only give advice on which license is right for you. The final judgment, of course can be made only by a court of law. With that said, we recommend the commercial license to all commercial and government organizations. This frees you from the broad and strict requirements of the GPL license.

To all free software enthusiasts we recommend our products under the GPL license. We believe that MySQL AB is one of the world's largest companies that offers all its software under the GPL license.

To anyone in doubt, we recommend the commercial license. It is never wrong. Thanks to our costeffective way of producing software, we are able to sell our commercial licenses at prices well under the industry average.

## Older Versions

Note that some older versions of the MySQL database server (prior to 3.23.19) are using the . See the documentation for the specific version for more information.

## When in Doubt

If you have any questions on MySQL licensing, feel free to contact us:

## G GNU General Public License

Version 2, June 1991  
Copyright © 1989, 1991 Free Software Foundation, Inc.  
59 Temple Place - Suite 330, Boston, MA 02111-1307, USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

**23.4 Preamble** The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute

copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

---

[Page EULA-19]

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

## 23.5 TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

1. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you". Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

2. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program. You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

3. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

1. You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

2. You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

3. If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it. Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program. In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

4. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

1. Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

2. Accompany it with a written offer, valid for at least three years, to give any third-party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

---

[Page EULA-20]

3. Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable. If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

5. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

6. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

7. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

8. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a

patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program. If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances. It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice. This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

9. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

10. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns. Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

11. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

## 23.6 NO WARRANTY

12. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/ OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

13. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

## 23.7 END OF TERMS AND CONDITIONS

### 23.8 How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

one line to give the program's name and a brief idea of what it does.

Copyright (C) yyyy name of author

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 59 Temple Place - Suite 330, Boston, MA 02111-1307, USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

Gnomovision version 69, Copyright (C) 19 yy name of author  
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type 'show w'.  
This is free software, and you are welcome to redistribute it under certain conditions; type 'show c' for details.

The hypothetical commands 'show w' and 'show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than 'show w' and 'show c'; they could even be mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the program

---

[Page EULA-22]

'Gnomovision' (which makes passes at compilers) written by James Hacker.

signature of Ty Coon, 1 April 1989  
Ty Coon, President of Vice

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

## License Agreement and Limited Warranty

The software is distributed on an "AS IS" basis, without warranty. Neither the authors, the software developers, nor Prentice Hall make any representation, or warranty, either express or implied, with respect to the software programs, their quality, accuracy, or fitness for a specific purpose. Therefore, neither the authors, the software developers, nor Prentice Hall shall have any liability to you or any other person or entity with respect to any liability, loss, or damage caused or alleged to have been caused directly or indirectly by the programs contained on the media. This includes, but is not limited to, interruption of service, loss of data, loss of classroom time, loss of consulting or anticipatory profits, or consequential damages from the use of these programs. If the media itself is defective, you may return it for a replacement. Use of this software is subject to the Binary Code License terms and conditions at the back of this book. Read the licenses carefully. By opening this package, you are agreeing to be bound by the terms and conditions of these licenses. If you do not agree, do not open the package.

Please refer to end-user license agreements on the CD-ROM for further details.

## Using the CD-ROM

The interface to the contents of this CD is designed to start automatically through the **AUTORUN.EXE** file. If a startup screen does not pop up automatically when you insert the CD into your computer, double click on the welcome.htm file to launch the Student CD or refer to the file **readme.txt** on the CD.

## Contents of the CD-ROM

- Java™ 2 Platform Development Kit, Standard Edition Version 5.0
- BlueJ Version 1.3.5
- JCreator™ LE Version 3.10 (Windows Only)
- jEdit Version 4.1
- jGRASP Version 1.7.0
- NetBeans™ IDE Version 3.6
- Live code examples from the book *Small Java™ How to Program, 6th Edition*
- Web Resources -- Links to internet sites mentioned in the book *Small Java™ How to Program, 6th Edition*
- MySQL® Version 4.0.20
- MySQL® Connector/J Version 3.0.14
- Apache Tomcat Version 5.0.25
- Additional material (in the Adobe® Acrobat® PDF format) not included in the book

# Software and Hardware System Requirements

- 500 MHz (minimum) Pentium III or faster processor
- Microsoft® Windows® XP (with Service Pack 2), Windows XP Home, Windows 2000 Professional (with Service Pack 4), Windows 98 (1st and 2nd Editions), Windows ME, Windows Server 2003, or
- One of the following Linux distributions: Red Hat 9.0, SuSE 8.2, or TurboLinux 8.0
- 256 MB of RAM (minimum), 512 MB of RAM (recommended)
- CD-ROM drive
- Internet connection
- Web browser, Adobe® Acrobat® Reader® and a Zip decompression utility
